In recent years, many branches of literary linguistics have taken a 'cognitive' turn, including narrative, so that this new approach merits an article of its own (*see* **Narrative: Cognitive Approaches**). Distinct from the latter are those studies rooted in linguistic pragmatics and philosophy, which attempt to specify the basic types of logical, informational, and evaluative inferences that story processors must use in comprehension. The study of inference making and inference triggering seems likely to grow in importance, not least because it broaches the daunting but essential task of modeling aspects of the interaction between situated discourse and what is sometimes called 'background knowledge' but has recently been dubbed 'impliculture' (Bhaya Nair, 2003).

Labov and Waletzky, 1967

In the sociolinguistic quest to 'tap the vernacular', one of the richest sources of data comes from narratives of personal experience (Labov, 1972; Labov and Waletzky, 1967). As the narrator becomes immersed in the details of the narrative itself, he is "no longer free to monitor his own speech as he normally does in face to face interviews" (Labov, 1972: 355), hence mitigating the 'Observer's Paradox' (Labov, 1970: 32). Thus, this type of data provides a wealth of largely unmonitored speech amenable to analysis of variable lexical, phonetic, and morphosyntactic forms. However, these narratives of 'ordinary people' (Labov, 1997: 397) which are commonplace in sociolinguistic data, have a more intrinsic interest: the internal structure of the narrative itself. These funny, tragic, trivial tales may appear to be idiosyncratic to the individual narrator, but despite their disparity vis-à-vis content and style, similarities in linguistic structure and function abound.

In an attempt to uncover the underlying mechanisms at work in the course of telling and retelling narratives of personal experience, Labov and Waletzky (1967: 12) propose an analytical framework which isolates "the invariant structural units which are represented by a variety of superficial forms." In other words, the deep level structures which map onto surface-level variations. Although this framework is nearly 40 years old, it "continues to dominate the field," (Macaulay, 2002: 289) alongside more wide-ranging treatments of narrative (e.g., Prince, 1983; Linde, 1993). It has thus remained the bedrock for sociolinguistic narrative analysis over the last few decades.

Fundamental to this framework is (1) the clause as a grammatical unit, and (2) the semantic functions of these clauses. The individual clauses are grouped into sections which have different functions within the story. Labov (1972: 359–360) defines narrative as "one method of recapitulating past experience by matching a verbal sequence of clauses to the sequence of events which ... actually occurred" (see also Labov and Waletzky, 1967: 201). A minimal narrative contains "a sequence of two clauses which are temporally ordered" (Labov, 1972: 360–361), as in (1) and (2):

(1) and I took his nappy off
and as I took it off literally he pooped all over the cubicle!
(2) and then his mum and dad woke up
and Mel punched his dad

(All examples come from a large number of narratives collected at the University of York (Smith *et al.*, 2002–2004) by students enrolled in the course Variationist Narrative Analysis).

These chronologically ordered clauses, or **complicating actions** (Labov and Waletzky, 1967: 32) provide the **referential** function of the narrative, reporting 'a next event' in response to the potential question 'What happened [then]?' (Labov, 1997: 402). They provide the backbone of the story and are the 'most reportable event' (Labov, 1997: 404): without these, there is no narrative. (The complicating action is often terminated by a result or resolution, "the set of complicating actions that follow the most reportable event" (Labov, 1967: 414).

However, most narratives are not this minimal, and, significantly, one "which serves this [referential] function alone is abnormal: it may be considered an empty or pointless narrative" (Labov and Waletzky, 1967: 13). In addition to the question 'What happened next?', we also want to know 'What's the point?'. Labov refers to this as the **evaluative** function of the narrative.

Evaluation clauses in a narrative contain statements or words that tell the reader what to think

Labov and Waletzky, 1967

In the sociolinguistic quest to 'tap the vernacular', one of the richest sources of data comes from narratives of personal experience (Labov, 1972; Labov and Waletzky, 1967). As the narrator becomes immersed in the details of the narrative itself, he is "no longer free to monitor his own speech as he normally does in face to face interviews" (Labov, 1972: 355), hence mitigating the 'Observer's Paradox' (Labov, 1970: 32). Thus, this type of data provides a wealth of largely unmonitored speech amenable to analysis of variable lexical, phonetic, and morphosyntactic forms. However, these narratives of 'ordinary people' (Labov, 1997: 397) which are commonplace in sociolinguistic data, have a more intrinsic interest: the internal structure of the narrative itself. These funny, tragic, trivial tales may appear to be idiosyncratic to the individual narrator, but despite their disparity vis-à-vis content and style, similarities in linguistic structure and function abound.

In an attempt to uncover the underlying mechanisms at work in the course of telling and retelling narratives of personal experience, Labov and Waletzky (1967: 12) propose an analytical framework which isolates "the invariant structural units which are represented by a variety of superficial forms." In other words, the deep level structures which map onto surface-level variations. Although this framework is nearly 40 years old, it "continues to dominate the field," (Macaulay, 2002: 289) alongside more wide-ranging treatments of narrative (e.g., Prince, 1983; Linde, 1993). It has thus remained the bedrock for sociolinguistic narrative analysis over the last few decades.

Fundamental to this framework is (1) the clause as a grammatical unit, and (2) the semantic functions of these clauses. The individual clauses are grouped into sections which have different functions within the story. Labov (1972: 359–360) defines narrative as "one method of recapitulating past experience by matching a verbal sequence of clauses to the sequence of events which ... actually occurred" (see also Labov and Waletzky, 1967: 201). A minimal narrative contains "a sequence of two clauses which are temporally ordered" (Labov, 1972: 360–361), as in (1) and (2):

(1) and I took his nappy off
and as I took it off literally he pooped all over the cubicle!
(2) and then his mum and dad woke up
and Mel punched his dad

(All examples come from a large number of narratives collected at the University of York (Smith *et al.*, 2002–2004) by students enrolled in the course Variationist Narrative Analysis).

These chronologically ordered clauses, or **complicating actions** (Labov and Waletzky, 1967: 32) provide the **referential** function of the narrative, reporting 'a next event' in response to the potential question 'What happened [then]?' (Labov, 1997: 402). They provide the backbone of the story and are the 'most reportable event' (Labov, 1997: 404): without these, there is no narrative. (The complicating action is often terminated by a result or resolution, "the set of complicating actions that follow the most reportable event" (Labov, 1967: 414).

However, most narratives are not this minimal, and, significantly, one "which serves this [referential] function alone is abnormal: it may be considered an empty or pointless narrative" (Labov and Waletzky, 1967: 13). In addition to the question 'What happened next?', we also want to know 'What's the point?'. Labov refers to this as the **evaluative** function of the narrative.

Evaluation clauses in a narrative contain statements or words that tell the reader what to think

about a person, place, thing, event, or entire experience. They are "the means used by the narrator to indicate the point of the narrative, its *raison d'être*: why it was told, and what the narrator is getting at" (Labov, 1972: 366). They give the story reportability and make it worth telling. These clauses can be highly embedded within the narrative itself and can include evaluation of a third person as in (3).

(3) And so he said in future years he'd only shag actresses.

On the other hand, it can be a much more direct statement about the narrator's feelings, as in (4):

(4) They've just got absolutely no scruples about owt.

The circumscription of evaluation, both structurally and semantically, has proved to be the most problematic. Its defining qualities underwent substantial revision in Labov (1972) and Labov (1997).

Added to the referential and evaluative function of narrative are orientation, abstract, and coda.

The **orientation** section of a narrative contains statements that provide the setting or context of a narrative which "serve to orient the listener in respect to person, place, time, and behavioral situation" (Labov and Waletzky, 1967: 32), as in (5):

(5) and he used to drink Lowenbrau
and he used to like ten pints every night
and at the weekends he'd get so drunk he couldn't stand up.

The **abtract** "is an initial clause that reports the entire sequence of events of the narrative" (Labov, 1997: 402) in summary form, as in (6):

(6) Last time I got pulled it were for drink driving.

In other cases, they are requests for an extended turn at talk, as in (7):

(7) So did you hear about the gas leak?

These often act as some type of advertisement in order to 'get the floor', as in (8):

(8) Right, I can tell you a birthday story and a half!

The *coda* is "a functional device for returning the verbal perspective to the present moment" (Labov and Waletzky, 1967: 39). These clauses often employ deixis, as in (9), or make the effects of the narrative applicable to the here and now, as in (10):

(9) Erm, and that was it. That was me getting arrested for fraud.

(10) So we live and learn and I shall never ever move a static caravan again.

These five major sections most often follow a linear structure: the story opens with the abstract, followed by some orientation clauses and then the complicating action, while the coda signals closure. Evaluation clauses are interspersed throughout this bounded unit.

In discourse level phenomena, "narrative is the prototype, perhaps the only example of a well-formed speech event with a beginning, a middle, and an end" (Labov, 1997: 396). Moreover, they have "a fairly regular structure that is largely independent of how they are embedded in surrounding talk" (Schiffren, 1994: 284). Although there are differences, both structurally and functionally, in how a narrative is realized, the study of a large body of narratives have demonstrated that this structure is fundamental to the majority of narratives of personal experience, it is the 'normal form' (Labov and Waletzky, 1967: 40).

Sociolinguistic Correlates

Although Labov and Waletzky's prime motivation in the 1967 paper was the narrative itself, one of the 'ultimate aims' was to "require close correlations of the narrator's social characteristics with the structure of their narratives" (Labov and Waletzky, 1967: 13). Since that time, a number of classic sociolinguistic categories have been examined against the backdrop of narrative: in particular class, gender, geography, age, and ethnicity.

Class

Labov (1997: 412) observes class differences in narrative: upper middle class speakers report on emotions, while lower class speakers "are sparing in their reporting of subjective feelings." Horvath (1987: 219) also finds differences in content: the majority of working class speakers' stories concern themselves and other family members; in middle class speakers' narratives, protagonists not personally known to them predominate.

Class differences may also exist not only in content, but in quantity, too. Macaulay's (1991: 139) study of Ayr in South West Scotland shows that working class speakers have on average a greater number of narratives both in number terms and as a proportion of the overall sociolinguistic interview than their middle class counterparts. This finding was replicated in his study of Glasgow speech (Macaulay, 2002: 298).

Gender

Labov and Waletzky make no explicit reference to gender differences in narrative, but it, too, may have an impact on content. Findings from Johnstone's

(1990: 66) study of middle class whites in Fort Wayne, Indiana, suggests that men's narratives focus on their personal exploits and successes, whereas women underplay the 'protagonists' personal roles.' Holmes' (1997: 286) results from the Wellington Corpus of Spoken New Zealand English are similar: "the women focus on relationships and people, affirm the importance of their family roles, family connections, and friendships. The men focus on work and sport, events, activities, and things, and affirm the importance of being in control, even when they don't achieve it."

Cheshire's (2000) research into the narratives of teenage friendship groups in Reading also finds gender stratification in how stories are co-narrated: in a nutshell, "for the boys, the telling was the more salient aspect of a narrative, whereas for the girls it was the tale" (Cheshire, 2000: 200).

Age

Labov (1972: 393–396) finds that the ability to narrate evolves with age. This is supported in subsequent research (e.g., Peterson and McCabe, 1983; Bamberg, 1897; Toolan, 1988). 'Leap frog' narratives are the most common among four year olds where the child jumps from event to event unsystematically. By six years old, the classic pattern established by Labov is more in evidence: temporal relationships have developed, but the referential function predominates, with little evaluative function evident (e.g., Peterson and McCabe, 1983), and a paucity of orientation clauses (e.g., Snow and Imbens-Bailey, 1997). In later years, there is a focus away from factual information to getting the point across, with an increasingly sophisticated use of evaluative devices with increasing age (e.g., Romaine, 1985; Kernan, 1977: 101).

Syntactic complexity increases with age from preadolescent to adult (Labov, 1972: 393), and remains stable in later years (Labov and Auger, 1993).

Ethnicity

Labov and Waletzky (1967: 38) state that their proposed framework "will achieve greater significance when materials from radically different cultures are studied in the same way." Indeed, whether their framework is culture specific or universal has been the subject of scrutiny (e.g., Tannen, 1981, 1982, 1984; Blum-Kulka, 1993; Tsitipis, 1988). Divergences from the 'expected' model appear from the very earliest years. Michaels (1981, 1984, 1985) shows that "children from different backgrounds come to school with different narrative strategies" (Michaels, 1981: 423). White children have as a framework 'topic-centered' narratives which have minimal assumption of shared background, full description of objects, explicit spatiotemporal grounding; black childrens' narratives are 'topic associating,' where the narrator presents "a series of implicitly associated personal anecdotes" (Michaels, 1981: 429). Ethnic differences are not restricted to children: Holmes (1997) finds in her New Zealand corpus that Maori speakers, in comparison to their Pakeha counterparts, leave parts of the narrative relatively inexplicit, including the evaluation section.

Geography

Johnstone (1990) suggests that there are regional differences in discourse style explicable in terms of different cultural contexts. In her analysis of Indiana narratives, she finds that the narrators use highly specific details, or 'extrathematic orientation' (Johnstone, 1990: 201) in orientation sections of narratives. She interprets this within the context in which the narratives take place: they must be culturally embedded, or 'anchored in the real, local world' (Johnstone, 1990: 210) in order for the narratives and narrators themselves to sustain, in Labov's (1997: 407) terms, credibility.

Linguistic Internal

The syntactic correlates of narrative structure are discussed in Labov and Waletzky (1967) and Labov (1972). Hopper (1979) and Hopper and Thompson (1980) also find that certain linguistic forms predominate in particular parts of the narrative: complicating action verbs are most usually punctual rather than iterative or durative and are usually perfective; stative predicates predominate in orientation; evaluation clauses are often irrealis, with use of modals, subjunctives, and negatives (see also Silva-Corvalán, 1983). These "predictable grammatical correlates not only for narrative type but also within narratives" (Fleishman, 1985: 852) are realized formally in some languages: for example, in Swahili, foregrounded clauses or complicating actions are marked with the prefix ka-, background with ki- (Hopper, 1979: 213). In other languages such as English, they derive from the discourse structure itself (Hopper, 1979) and are used as devices to signal levels of 'information relevance' (Fleischman, 1985: 852).

Variable morphosyntactic forms that cannot be explained at clause level may find interpretation within the broader discourse unit of the narrative. Schiffren (1981) finds hardly any use of the historic present in abstracts, codas, and evalulative clauses, and a minimal number in orientation. In contrast, almost one-third of complicating action clauses are in the historic present. The interpretation of these

quantitative results relies on Labov and Waletzky's model: as verbs in complicating action clauses are temporally ordered, they are free from providing a reference time, thus marking for tense is redundant (see also Johnstone, 1987; Wolfson, 1979; Silva-Corvalan, 1983).

Despite some findings on differential behavior across a range of sociolinguistic and linguistic internal categories, the foundations of Labov and Waletzky's framework remain largely unchallenged. In the field of sociolinguistics, they continue to provide a solid foundation for research into narratives of personal experience.

Narrativity and Voice

M Bal, University of Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

'Voice' concerns the question 'Who speaks?' (who tells the story in a narrative?) and presupposes a pragmatic view of language. Hence, the concept of voice implies that any narrative is uttered by someone. Usually, one speaks of narratives 'in the first person' when the voice refers to itself and 'in the third person' when it does not and the narrative appears to just flow (Bal, 1996). More rarely, narratives are told 'in the second person,' so that the first person is strongly implied but not mentioned. An intermediate form is 'free indirect discourse,' where the narrative espouses the idiosyncrasies of the character closely without using the first-person pronoun. Voice is the concept that, in the wake of Roland Barthes, killed the author while enabling critics to continue analyzing texts by positing a 'speaker' who allegedly uttered them. At the time, many were preoccupied with the French tradition, and I was myself interested in emending Gérard Genette's theory of narrative. At this time, I want to give some opacity to the perhaps too transparent veil of these alternative approaches, so that it helps to cast a somewhat amazed look at that key concept of voice. I will deprive the concept of its 'naturalness' and refrain from taking it for granted. Instead, I argue that 'voice' is an extremely artificial and skewed concept.

This reversal of what is 'normal' or 'natural' and what is *techne* or artifice accomplishes three things. It helps to suspend – but not give up – what seems 'normal' or even 'natural' in the equipment we have inherited from our training and from the traditions within which we work, including the concepts of voice and others we routinely work with and the methods learned and practiced. It suspends the certainties regarding the domains the humanities have accustomed all of us to consider **separately**: art, literature, film, and the ideas and images that run through philosophy and religious studies. Moreover, it questions the concept of voice as one borrowed from the domain of the **anthropomorphic imagination** and as deriving its apparent self-evidence from it.

Voice and Its History

The metaphor of 'voice' in literary studies came into use after the 1930s, in the wake of certain technological discoveries and developments. Neither of the two earliest modern publications considered narratological – the collection of Henry James's prefaces to *The art of the novel* from 1907 and E. M. Forster's *Aspects of the novel* from 1927 – uses the term. James uses a remarkably **visual** vocabulary, whereas Forster uses the term 'story-teller' (Forster, 1974: 22–23) to refer to the author of narrative literature. When he uses the term 'voice,' he is referring either to tone ('a tone of voice' (Forster, 1974: 86)), or to the literal, physical voice. For example, he writes: "... the story as a repository of a voice. It is the aspect of the novelist's work which asks to be read out loud." (Forster, 1974: 27) But, though he does not use the concept in the analytical sense of later narratologists and linguists, his phrasing tells of the transforming meaning of voice in a culture about to embark on a 'secondary orality,' as radio and sound film became common. He writes, with a tellingly enthusiast primitivism:

> What the story does do in this particular capacity [...] is to transform us from readers into listeners, to whom 'a' voice speaks, the voice of the **tribal** narrator, squatting in the middle of the **cave**, and saying one thing after another until the audience falls asleep among their offal and **bones** (Forster, 1974: 27, emphasis added).

The late 1920s and the 1930s would be the moment that the word 'voice' became replenished with sense and relevance in a culture that saw itself as modern. It is the moment that posed the problem of voice in the culture at large. Specifically, it was the moment, heavy with consequences, in the middle of the so-called modernist period, of the transition from silent to sound film (see Lastra, 2000).

Before that transition, the idea that images could have a voice was as utopian as it was exotic. The 'movement' of the image was already quite an impressive miracle, for which artists like Degas and photographers like Muybridge and Marey had prepared the public. To turn technological experiments into multimedia spectacles, pianos were put in the theater room. Sound was a luxury – decorative. It did not narrate. But one day, technology facilitated the transition that we now find so natural – from silent to sound film.

This was not a single transition. The particular moment I am interested in here is when sound began to transform from ornament to supplement, and before it became an integral element of the moving image. It is the moment when sound began to be 'added' to the image. The image was made first, and then sound was literally put together with it. The procedure of adding sound was jokingly called 'goat-glanding' (Armstrong, 1998). A generation later, the true wonderment of the procedure, its technological spectacularity soon forgotten, was evoked

nostalgically in fictional form in the film *Singin' in the Rain* by Stanley Donen and Gene Kelly (1952; see Armstrong, 1998). This film can serve here as a theoretical object and contribute to an understanding of the full impact of the concept of 'voice,' which is not taken into account when it is used for narrative analysis.

In this film, play-acting without words, the 'original' or 'natural' form of the moving image is represented in all its fantastic splendor when Debbie Reynolds acts as an acoustic prosthesis to the 'mute' actress whose voice wouldn't 'pass.' Whereas Reynolds ends up achieving final victory, the class-bound censorship of her counterpart's voice exceeds the hilarious humor of the set-up of doubling and splicing between body and voice. It also puts the finger on what may well be called 'the politics of voice,' which would link this 'classism' to Forster's primitivism. In line with Schmid's narratological concept, we could speak here of 'voice-interference.'

'Goat-glanding' opened the possibility of a new engagement between language and image. This new engagement turned cinema into the third art. Neither literature nor visual art nor a simple combination of the two, cinema was a fundamentally different art where language and image were inextricably intertwined, along with other media such as music and space. From that position, cinema was able to cast doubt on the essentialism that sought to separate the media and consequently house them in separate disciplines.

In this culture, cinema had the role of cultural model that we are only now beginning to grant it, in its break with the idea of 'pure' media and its accession to the mass public, which accorded the masses the status of both consumer and **judge** of art. But this cultural situation also generated a crisis. I contend that the concept of 'narrative voice' is an instrument of the **repression** in that crisis and the crisis of authorial authority that it entailed.

This cultural crisis, which knocked absolute authority out of the hands of expertise, is also the crisis of the authority of the author. Barthes and Foucault drew only philosophical consequences from the technological change, and that, quite late, when they proposed the ideas of the dispersion (Foucault, 1979) and death (Barthes, 1986 [1968]) of the author. The moment of crisis had, in fact, already happened several decades before. The trigger was the cinema, recently furnished with a voice.

The metaphor of voice as technological would, for example, direct attention to the production of the 'diegetic chronotope' – the timespace in which the plot is set – as the domain of the effect of the real. Far from possessing an authority that goes without saying, narrative voice seen as 'addition' distracts attention from the total lack of authority of, to recall the example, Debbie Reynolds' character, in order to implement the diegetic fiction as the frame of viewing the work as a whole. That fiction draws the story into a chronotopological hole, from which, in general and with the exception of postmodern experimentation, it will not reemerge.

In this respect, again, the literalized revelation in the raising of the curtain in *Singin' in the Rain*, with its explicitly added voice, can serve as model. The identity of the woman 'who speaks' shows itself in a *mise-en-scène*, which is also a theoretical *mise-en-abîme* of the question, 'Who speaks?' Here, the *mise-en-scène* 'explains' why, in the history of cinema, the artificial character, the nonidentity, the 'added' quality of the voice, has been 'forgotten' so easily, so fast, and perhaps, so desperately.

In the cinema of former days, this technology had had its own materiality: sound, music, tools, and machines. But a new cognitive understanding also underlay that very materiality whose conception it had made possible because thinkable. That understanding is anchored in the sciences of the time. It concerned not the overestimation but rather the fundamental deficit of the body, so that it was seen as being in constant need of supplementation by means of prostheses, one of which was the voice. The concept of voice, disembodied, made technical, thus makes its appearance as a tool for analysis, as if to over-compensate for the anxiety triggered by a generalized sense of the body's defective state. A body part pried loose of its body.

In view of the fiction that proclaims the disincarnation of narration, one must take a position in the debate that subtends such an attitude towards voice. On the one hand, the concept of narrative voice is constructed on the presupposition of spatial distance. By not matching the images in any obvious way, the voice seems to lose its body. This loss brings it into the present of reading, where it partakes of the strong perceptual and affective experience. This, in turn, reincarnates the voice. But, on the other hand, in the very attempt to incarnate it, to give it body – for example, by marking its gender, age, and other social positions – the voice is deindividualized by the analyst who uses the term 'voice.'

Faced with these cases, where the concept of voice is artistically theorized as meaningful after all, it is necessary to 'work through,' put under erasure, those aspects of the metaphor of voice that distort and censure the analysis.

Images of Authorship

Among the aspects of the metaphor of voice that might have informed its creation and that remain its primary motor, is, first of all, the notion of the 'subject' as the owner or site of the narrative voice. This incites the analyst to privilege voice over other aspects of the fabric of the narrative text that contribute equally strongly to the production of its meaning. Most obvious of all is the example of the 'image.' The text is not reducible to the ensemble of words that constitute it. The image is an element in all narratives. The narrative voice entertains a relationship with the visual fabric that permeates the text, but this is not a systematic relation of mastery.

The narrative voice does not 'create' or produce all the images rendered in the text; many preexist the voice's description of them. 'Voice' is a term invented to eliminate authorship as the prime preoccupation of literary studies, yet to let it in again through the back door. Wayne Booth published a book in 1961 called *The rhetoric of fiction*. As the title indicates, two elements of what constitutes the field or object 'literature' in the common understanding orient it away from the author's primacy: 'rhetoric' and 'fiction.' The one indicates that whoever 'speaks' the words in the text does not speak straightforwardly in a direct, reliable, constative mode of language use, but may be caught in acts of seduction, deviation, figuration, or outright lying. Hence, the second element, 'fiction,' which takes literature away not only from the author but also from the world within and for which she writes. Appealing to a mode of reading still most adequately defined as 'the willing suspension of disbelief,' fiction takes the substance, content, or reality of the literary work out of the hands of the author. The latter can wash her hands of everything that shocks, disturbs, annoys, or dangerously entices the reader. The latter, as the definition has it, is responsible for willingly giving up on the author's epistemic answerability.

Booth's book introduced a term – the 'implied author' – that from that moment on was so widely used that it became a cliché. The term is deceptively straightforward. It suggests that the biographical author has a textual delegate behind which she can hide, a guarantee of discretion and cultural politeness morphed into a methodological *de jure* argument. But the concept *de facto* operated the switch, not really from author to text but from author as speaker of the text to reader who construes an image of that person. The reading, the concept promised, would give all information, relevant and desired, about who 'spoke' the narrative. Any questions beyond who wrote the book were indiscreet and redundant. Inscribed within the text by a 'hand' she could manipulate at will, the author could be read off the page, and it befell to the reader to compose the image of the author from the data gleaned during the reading.

The 'implied author' offered a bonus that the author as corpse did not, and that became too attractive to turn down. In a quite literal double sense, it **authorized** the interpretation one wished to put forward without taking responsibility for it. The phenomenological edge of the concept wore off. What was left was the authority of the constative statements that speaking of – but simultaneously **for** – the implied author afforded. Judgments based on the idiosyncrasies of individual readings could be presented with the aura of having detected what the author, willy-nilly, 'meant to say.' Meaning thus collapsed into intention, as it had before Booth came along.

Meanwhile, a mere seven years later and in a totally different vein, Roland Barthes had put the author to death, given birth to the reader, and conjured up a phantom author rather comparable to Booth's. The author whose death he hyperbolically declared was the masculinist, individualist bossy one of classical narrative and its obedient theorists. Instead, between the lines of his murderous prose, he proposed a figure without identity or voice, an impersonal 'scriptor.'

Neither Booth, who displaces the author into the realm of interpretation, nor Barthes, who attempts to disembody the author, eradicates this figure. It appears as if the author cannot be entirely dispensed with. For the moment, it seems preferable to just bracket 'him' and look at the results of these rhetorical moves.

Once the author is bracketed and reemerges on the reader's side of things, the first major problem that this move leaves hanging is the question of 'who speaks' the words on the page if it isn't the actual author. The first step, further away from the now rhetorically built author, was the concept of 'narrator.' This addition was necessary because a single narrative, by definition attributed to a single implied author, can easily have many narrators. Also, a narrative 'in the first person' sometimes speaks with the voice of the younger self, and then with the one of the disabused older fellow who decides to write down the life story.

In search of reliable concepts, yet intent upon conceptualizing agency 'beyond' the author, literary studies reformulated the question of 'who speaks' as the question of 'voice.' The word 'voice' is naturalized, a near-catachresis, to account for the fact that a story

doesn't come out of the blue, and that someone is responsible for it. As such, it seems indispensable to circumscribe the subject of the text. But when we use words like 'responsible,' we enter the domain of the ethical.

Related to this responsibility is yet another aspect of voice – as metaphor of textual subjectivity. This metaphor is also the starting point of a search, of the 'whodunit' kind, the quest for the identity of the unknown criminal. This question indicates that words and images matter, that they 'act,' as speech-act theory teaches us. Where acts are performed, someone is accountable; the entire social and legal system works on that premise. No wonder the disciplines that comprise the humanities also take for granted the importance of that fundamental question.

The question 'Who speaks?' interrogates the nature of the verb 'to speak.' This question implies two questions about meaning. The first concerns the construction of meaning. 'What does this mean?' and 'What does she mean (to say)?' are two different conceptions of meaning that the metaphors of authorship conflate, namely signification – the production and processing of publicly accessible meaning – and intention – that inevitable urge to identify meaning with the mind of the genius-artist who put that meaning out. The former has no bearing on authorship; the latter does. Conflating them, then, begs the question of meaning.

The second question implied in the 'Who' question concerns agency. 'What are the consequences?' is perhaps the best way of phrasing it. This question raises two others: on the one hand, that of the effectivity measurable only in terms of reception, in other words, what does the work 'do' to its readers or viewers?, and on the other hand, the social relevance of the work, that is, 'What does it do to the public domain in which it functions?' These two questions, I hasten to add, must be asked in the positive but also in the negative form. What meanings and critical possibilities are repressed when we use a concept of the 'who?' kind, such as narrative voice? In other words, what is the metaphorical status and import of the analysis structured on the basis of 'voice?' In anticipation of my conclusions, this need to ask the question 'who?' negatively – which is rarely done – makes it impossible to dismiss the personification implied by the question.

Conceptions of the Artistic Text

A second cluster of features imported by the metaphor of voice concerns not the subject of the work but the conception of art that underlies it. The privilege mostly unreflectively accorded to narrative voice easily entails an extreme 'mimeticism,' an assumed and endorsed, albeit disavowed, seamless match between social relations and literature, a match that is literature and art's very mission to question. The relevance of literary narrative resides, precisely, in its refusal to obey the pressure of realism as *trompe-l'œil*. The question of 'who speaks?' can only escape that *trompe-l'œil* if its other, the question of 'who doesn't speak?', is systematically carried on its back, like a parasite. The question of which character, in what social position, does **not** have access to speech, is, on the one hand, one of voice, but on the other, one that undermines the belief in and obedience to the text as 'account.' As Gayatri Spivak remarked in a brief but forceful analysis of the case of Friday in Defoe's *Robinson Crusoe*, (1975 [1719]) – later revisited by Coetzee's *Foe* (1986) – Friday's tongue has been cut (1999: 186–187). In Coetzee's postmodern version, his tongue has been cut literally, hence, physically. This mutilation can, in and of itself, serve as a theoretical object. It stages an almost naïvely literalizing perspective on Defoe's story in a rewriting that is disabused of realism.

The addictive attachment to realism is rooted in the need to protect the aspect of the metaphor of voice that most badly needs scrutiny, namely authority. Authority is both obliterated and protected – and abducted by a criticism that nevertheless derives its authority from it. As I mentioned above, the presence of authority in humanistic studies allows the authorization of interpretation to be naturalized. The concept of voice, hence of narrator, is part of that authorizing impulse. As a phantom presence, the author continues to lurk in the wings as long as the major analytical concepts partake of the author's anthropomorphic shape. The attribution of intention that this concept of narrator facilitates is a weapon in the service of subordinating the reader. The latter, brainwashed by education to interiorize the taboo on exercising her function of 'second person,' is too easily submissive to the intention that clothes the text as long as it is conceived as the unquestioned product of voice. But, I contend, 'below' or 'behind' the thematic of narratorial sincerity, authenticity, and competence lies an alleged and naturalized unity of cultural memory in which those features are given the status of virtues.

Responsibility, in other words, does not equal authority. Both the scriptor and the reader are responsible for their acts of meaning-making, all the more so because they cannot appeal to and hide behind authority. Nor does subjectivity equal agency; one can exist as a subject and still be deprived of agency. Conversely, agency cannot take advantage of the problematization of unity to disavow responsibility. Here

lies the importance of a disbelief that undermines realism. Against the desire for authority that informs the addiction to mimeticism, and before a different kind of entanglement between reader and work becomes possible, a disentanglement of responsibilities is necessary.

Nor can voice claim 'origin,' that other doxic cultural obsession. Origin implies generativity, and that perspective must be kept in its limited place. If words and images 'come from' somewhere, it is from the culture that the work and its readers share, at least partially. They are picked up like graffiti and litter from the roads we walk along throughout our lives. They end up in works of art and literature. Then we hasten to narrow their provenance to the single speaker we call 'voice.' Mikhail Bakhtin insisted long ago on cultural polyphony, and many scholars have followed suit (*see* **Dialogism, Bakhtinian**). Against this craving for and self-evident alleging of origin, I suggest that voice insists too exclusively on illocution, that aspect of speech – and by extension, of all cultural utterances – that indicates the speaker's intent. In the process, it privileges the speaker, writer, or maker of images. Thus, the concept lends itself to subordinating and easily obscuring perlocution, the utterance's **effect**, and thereby disempowers the listener, reader, or viewer. We need to suspend **time**, in the sense of sequence, as narrative's defining principle, if only because of its obsession with the idea of origin. Together, then, the aspects of voice discussed so far – subjectivity, mimeticism, its grounding in authority, and origin – have in common a tendency to restrict narrative analysis to the inscription of time as foundation of narrativity. This remains important. The concept of 'voice' must remain functional, albeit 'under erasure.' But this temporality is located inside the chronotope that constitutes all narrative works.

Abstract:

The article presents the narratological key concept of 'voice' through two main paths. It positions the concept historically in the early days of cinema and modernist literature, and it offers a critical assessment of the implications of this concept. When one takes 'voice' as a conceptual metaphor, its implied connotations carry a heavy load of ideological presuppositions. Instead of dismissing it, however, the article recommends a use that is self-aware and refrains from endorsing these implications.

Biography:

Mieke Bal, a well-known cultural critic and theorist, holds the position of Academy Professor in the Royal Netherlands Academy of Arts and Sciences (KNAW). She is also a Professor of the Theory of Literature in the Faculty of Humanities at the University of Amsterdam. Her most recent book is *Travelling concepts in the humanities: a rough guide* (University of Toronto Press, 2002). Among her many other publications are: *Louise Bourgeois'* Spider: *the architecture of art-writing* (University of Chicago Press, 2001), *Quoting Caravaggio: contemporary art, preposterous history* (University of Chicago Press, 1999), and *Narratology: introduction to the theory of narrative* (2nd, revised and expanded edition) (University of Toronto Press, 1997). *a Mieke Bal Reader* is forthcoming from the University of Chicago Press. Her areas of interest include literary theory, semiotics, visual art, cultural studies, transcultural history, feminist theory, French, the Hebrew Bible, the 17th century contemporary culture, and art presentation. She is also a video artist.

Narratology, Feminist

R E Page, University of Central England, Birmingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Feminist narratology emerged as a distinctive area within narrative theory in the late 1980s. It might be understood as a response to classical narratology where earlier models and approaches are revisited and critiqued from a feminist perspective. In its broadest sense, feminist narratology embraces the study of narrative (including its formal features, interpretation, and function) with particular attention to the ways in which these might inform or be informed by aspects of feminist theory. However, defining what constitutes both 'feminism' and 'narratology' is not unequivocal, for both terms encompass a range of diverse positions. This has led to some debate as to the validity of feminist narratology. In its strictest sense, narratology might be understood as describing the abstract systems behind literary narratives, in which case feminist narratology has been deemed problematic for it is understood to be concerned with matters in the domain of application and interpretation (Diengott, 1988). However, the development and diversification of contemporary narrative theory have broadened its realms to include nonliterary texts and theoretical paradigms, thus incorporating the potential influence of feminism(s) in this enterprise. Like the multiplicity characterizing narrative and feminist theories, feminist narratology cannot be said to present a unified 'school'. Instead, work that might be considered under this umbrella term spans varied terrain. This is not *ad hoc*, but might be grouped together in distinctive streams. Each of these is discussed below.

Psychoanalytic Plot Dynamics

Feminist narratology has been usefully applied in studies derived from psychoanalytic theory that explore issues of plot dynamics. The premise underpinning this approach is that the trajectory of plot may be conceptualized in terms of desire, both of which then may be related to gender. Thus, Brooks characterizes the progressive rise and subsequent decline of tension in conventional, action-driven plot structure as the "male plot of ambition" (1984: 39). Feminist critics have sought to expose the gendered erotics behind this paradigm and instead have offered alternatives where the stereotypical characteristics of women's writing as repetitive, cyclical, or resistant to closure are associated with dynamics of desire grounded in explicitly female experience, such as breastfeeding, childbirth, and the female orgasm (Winnett, 1990). The corollary of this is a binary pairing of linear versus nonlinear plots, which is then transposed onto male and female values and experience. This opposition is not unproblematic, and though it reflects a second wave feminist impulse to identify difference and to recoup, indeed celebrate 'female' alternatives, this stream of feminist narratology has been critiqued in later years. In line with the shift away from essentialism, a recognition of the socially constructed nature of gender and an increased awareness of cultural diversity in feminist thought, these studies have been termed 'Eurocentric' and interrogated for their potential elitism (Homans, 1994). Furthermore, the psychoanalytic theory that these models draw on has itself been challenged in a variety of ways. In particular, the universal mapping of gender onto erotic desire or the death drive has been questioned. This has led to closer attention to the specific intersections of gender, plot structure, and cultural situation as they are manifest in specific texts and contexts.

Postclassical Narratology

A second, and highly influential, stream of feminist narratology is that which might be termed 'postclassical'. This work has followed the imperative given in Susan Lanser's seminal paper 'Toward a feminist narratology' (1986) to re-examine the classical models of narratology. As Lanser's groundbreaking paper indicates, the intersection of narratology and feminist theory exists as a dialectic relationship whereby *both* paradigms are informed and altered by the other. Studies in this area might be understood not only as illuminating texts by or about women in the light of narratological analysis (examples of applied narratology) but also as challenging or extending the narratological frameworks employed.

Central to this re-evaluation of classical narratology is the move away from structuralism's attempt to identify universal components of narrative (for example, Propp, 1968 [1928]; Barthes, 1977; Labov, 1972). In line with narratology's shift toward a more contextualist stance, postclassical feminist narratology seeks to understand the form and function of narratives in relation to specific texts and contexts. Underpinning this is a critique of the limitations imposed by corpora as seen from a feminist perspective. As Lanser puts it, "the narratives which have provided the foundation for narratology have been either men's texts or texts treated as men's texts" (1986: 343). Specific studies have pursued this matter further. Notable examples include the re-evaluation of

Labov's work on narratives of personal experience where the apparent neglect of gender as a salient speaker variable (at least in certain subsequent applications of his model) has been called into question.

The feminist application of narrative theory to texts by women has gone on to be far-reaching and highly fruitful, encompassing the re-evaluation of many different aspects of narratology. This includes studies of plot; closure; narration and voice; manipulation of time; reader response; focalization; and spatialization. Although the individuality of particular studies should not be underestimated, a general (although not unequivocal) trend found in this kind of approach has been to explore the distinctive character of these texts in relation to a binary model of gender. This is inherent in the direction indicated by Lanser's (1986) paper, which is shaped by the second-wave feminist emphasis on the difference of women's writing and speech. Significant collections of this kind of work include Mezei (1996).

Clearly, this postclassical re-evaluation has been a vital stage, not only in elucidating a range of texts that had been excluded from the canon but also in re-energizing aspects of narratology. However, shifts in feminist theory have now begun to have an impact on more recent approaches in feminist narratology. In particular, the influence of Butler's (1990) work has resulted in the replacement of a reductive, binary model with an acceptance of the potentially shifting and multiple nature of gender as performed by individuals in particular situations. The outworking of this has yet to fully emerge, but has included interpreting nonconventional narrative structures, intertextuality, and multiple voices as forms of performance (Page, 2003a).

Linguistic Studies

One of the proposed outcomes of feminist narratology as indicated by Lanser's paper was the exploration of whether or not women's writing of narratives differed from that of men and hence could be located as a separate tradition. This investigation of gender difference in relation to storytelling style may be paralleled with the analysis of 'nonliterary' narratives taking place in other research paradigms. Specifically, the sociolinguistic work that has come to be known as 'feminist linguistics' has included within it the study of women and men's conversational narratives. This may be considered as a third significant subfield of 'feminist narratology'. Work in this area has examined data from a range of cultures and contexts. The results of this indicate that, within certain contexts, there does seem to be a measure of evidence for women and men's differing use of linguistic features in storytelling styles. This has focused on specific areas, such as uses of evaluation (Page, 2002), humor (Eggins and Slade, 1997), the creation of narrative worlds (Johnstone, 1990), and the use of reported speech (Coates, 2000). Although they indicate points of difference, these studies caution against the simplistic mapping of isolated narrative features onto a single variable such as 'gender'. Rather, the trend has been to argue that speakers' use of narrative features might be seen in terms of performance where these features act as 'contextualization cues' for gender that may interact in complex ways with other potential influences such as class, ethnicity, or sexuality. Moreover, these studies are grounded in local contexts, from which abstracting a generalized conclusion about a definitive narrative style distinguished on the grounds of gender is seen as untenable.

The analysis of narrative and gender has also been influential in the study of identity in the social sciences, particularly as means of understanding the ways in which individuals use storytelling as a means of self-portrayal, a way to explore possible selves, and a way to negotiate alignment with their audience(s). Individual studies range across diverse areas from preschoolers' use of narrative (Kyratzis, 1999) to the construction of masculine identity (Coates, 2001). These studies reinforce many of the points made earlier, particularly that the correlation of gender and narrative features must be understood as dynamic and jointly constructed and reconstructed by those who produce and interpret narratives in particular contexts.

One further area of significance is the analysis of media narratives from a feminist perspective. These studies often draw on critical discourse analysis, but may use frameworks derived from narratology (focalization, evaluation, characterization) in conjunction with this in order to interrogate the relationships between form, content, and ideology. In contrast to the work on literary narratives, though these studies do point to the differences in the representation of groups of women and men, they are also concerned with the origins and sociopolitical ends to which these narrative representations may be put. For example, the objectification of women (constructing them as the 'focalized') might be understood as reflecting and maintaining the masculinist agenda of the media, thereby continuing to perpetrate gendered stereotypes with negative effects for women. This has been the subject of extensive work and intersects with research in media studies and discourse analysis. The data that have been analyzed include advertisements (Mills, 1995), magazine articles (Caldas-Coulthard, 1996), newspaper reports (Caldas-Coulthard, 1995;

Page, 2003b), and web pages (Chandler-Olcott and Mahar, 2003).

Although not strictly within the domain of feminist narratology as such, the intersection of feminism and narrative theory has also been highly influential in feminist film theory. Key theorists in this field are Mulvey (1975) and De Lauretis (1984), both of whom draw heavily on semiotics and psychoanalytic theory in their feminist interpretations of gender politics, desire, and pleasure in film. In particular, Mulvey's work developed a theory of the male gaze that argues that in its voyeurism, the structures of Hollywood cinema must be understood as patriarchal and therefore rejected by feminists. De Lauretis also focuses on the power dynamics inherent in the structures of narrative desire and, via psychoanalysis and semiotics, maps this gendered paradigm (male as agent, female as object) onto the processes of representation. As with the psychoanalytically inflected feminist narratology, this work has been subsequently critiqued for its essentialism and universalizing tendency, with later work calling for recognition of gender's intersection with other variables such as sexuality, race, class, and cultural context, thereby embracing feminism's increasing multiplicity.

Feminist narratology is thus a diverse enterprise that continues to expand along with narratology's influence. Despite this diversity, many of these studies reflect similar shifts in feminist thought. This includes the early preoccupation with exploring narrative in relation to gender difference in line with second-wave feminism; a contextualist position where gender is seen as one of multiple, intersecting variables that influence particular tellings in specific situations; and a third-wave understanding of gender as performed and shifting rather than a fixed, stable entity. As such, the feminist theory that has influenced this field includes both French feminists and those from the Anglo-American school. Feminist narratology's wide-ranging use in applications across disciplinary boundaries suggests that it is a field that will continue to shape and be shaped by changes in feminist thought and perspectives from other research paradigms.

Nationalism and Linguistics

What Is Nationalism?

Nationalism is the political expression of the notion that humanity falls naturally into distinct peoples or nations. As a political doctrine, nationalism is conventionally traced to Europe in the beginning of the 19th century (Kedourie, 1993). Nationalism has been characterized as involving the invention of "imagined communities" (Anderson, 1991), and the modern origins of political doctrine of nationalism are frequently contrasted with the claims of nationalists for the antiquity and historical continuity of their nation (Gellner, 1998). The historian Eric Hobsbawm argues that the criteria used for defining nations such as language and ethnicity are themselves "fuzzy, shifting and ambiguous" and thus "unusually convenient for the propagandist" (Hobsbawm, 1992: 6). This notion of nationalism as a purely artificial creation has been criticized as inadequate to an understanding of the preexisting cultures and bonds of kinship on which modern nationalism was often built (Smith, 1999: 8–9). Thus, some theorists of nationalism reject the notion that criteria such as a common language or common descent are purely subjective constructs. The terminology in relation to nationalism is notoriously problematic. For example the term 'nation' refers both to ethnic collectivities as well as to political states, and nationalism involves the interplay of many different and frequently interacting parameters of identity (religion, class, race and lineage, language, territory, history, etc.).

Linguistics and the Politics of Linguistic Diversity

One key element in the development of European nationalism was the politics of language, and the rise of a theory of identity based on mother tongue. The notion of linguistic identity that underlay the emergent European nationalisms of the 19th century became an immensely powerful political force, which was to rewrite the political map of Europe and much of the world. Humanity was conceived of as falling naturally into groups defined by language, and these groups were held to reach maximal self-expression in an independent state.

The extent and nature of the prehistory of modern linguistic nationalism is open to debate. Roman Jakobson (1945) argued that the ideal of a national language as having high cultural value was first formulated as an ideology in the Slavic world in the Middle Ages, and was not a product of the Western European Renaissance and Reformation as is generally assumed. This prehistory of linguistic nationalism is conventionally taken to include the translation of the Bible into the European vernaculars, the development of proto-national print cultures, and the decline of Latin as the pan-European language of scholarly exchange. The Protestant logic that required that the ordinary person should understand the language of the Bible and of the liturgy was ultimately applied to the language culture of the modern nation–state.

The prehistory and history of modern linguistics is intertwined with the emergence of linguistic nationalism, though one should note the strong currents of philosophical universalism running through linguistic theorizing in the West. One proto-nationalist strand involved 18th century debates about the interrelationship between language and national character (Morpurgo Davies, 1998: 114–118). A second strand concerned the status and standardization of vernacular languages, in particular in relation to their use in scholarly literary expression. Although in the late, highly professionalized phase of the discipline, linguists have tended to be wary of purism and other forms of normative discourse, historically language scholars played a central role in defining the boundaries between languages and promoting proto-nationalist or nationalist language engineering (Gottsched, 1758; Webster, 1789; Linn, 1997; Milroy and Milroy, 1991: 5–11).

To demonstrate the worth of the European vernaculars, scholars identified them with the language of the Garden of Eden (Olender, 1992). Alternatively, languages were assessed with reference to links traced back to the sons of Noah, i.e., Shem, Ham, and Japhet. The ancestor of the Europeans was held to be Japhet, and the term 'Japhetic' as applied to a language family was the precursor of the terms 'Aryan' and 'Indo-European.' In the framework adopted by James Parsons (1705–1770), the study of the 'striking affinity' or resemblance between the European languages was a means of distinguishing genuinely primitive, i.e., original languages, from mixed or derivative languages (Parsons, 1767). This model was based on the idea of "every one after his tongue, after their families, in their nations" elaborated in Genesis (10: 2). Gradually, however, the results of comparative linguistic analysis came to stand alone as observational truths within a secular science of language.

The comparative and historical study of language did not necessarily provide support for straightforward nationalist models, though it could be used for that end. There were many levels to the possible affinities between peoples and their languages, and the postulation of an original Aryan or Indo-European language implied a deeper kinship than the vernacular-based linguistic nationalism of modern European political culture. The inclusion of Sanskrit as one of these languages raised difficult historical questions about the relationships between territory, language, race, and the emergent European nation–states.

Like nationalism, modern or 'scientific' linguistics is conventionally said to have emerged as an independent discipline at the beginning of the 19th century, with the founding of historical and comparative linguistics. This emergent discipline inherited the Biblical concept of a nation or *Volk*, as a descent group sharing a common language and territory. This model was found in the influential theories of human diversity offered by Johann Gottfried von Herder (1744–1803) (1770) and Wilhelm von Humboldt (1767–1835) (1836), and in the nationalist understanding of the concept elaborated in Germany by Johann Gottlieb Fichte (1762–1814) in response to the Napoleonic conquests (1808). Romantic theories of organic community stressed the role of native language or mother tongue in self-fulfillment and self-expression and in defining the cultural and conceptual boundaries between human groups or nations. The modern discipline of linguistics continues to debate the issue of linguistic relativity in relation to the writings of Humboldt, Benjamin Lee Whorf (1897–1941), and others.

A proto-nationalist or nationalist understanding of language lay behind the canonical features of the study of language as an aspect of national culture, i.e., the comprehensive historical dictionary project, the modern grammar, the dialect atlas, and the history of the language. One can track the progress of self-conscious linguistic modernity with reference to such projects. The writing of the history of the vernacular languages, in parallel with national literary histories, often carried an implicit or explicit teleology of national liberation from the dominance of dynastic, clerical or foreign languages and from the categories of classical grammar.

The second half of the 19th century saw increasingly complex and contradictory models of human linguistic and racial affinity being proposed by European intellectuals, including linguists (Renan, [1882] 1990). Scholarly investigations of human history and affinity were assumed to have political consequences, in that they were capable of identifying true or natural bonds or ties of kinship underlying the complex surface affiliations of the contemporary world. Widely varying models and horizons of identity were debated. Some envisaged broad horizons of affinity (pan-Slavism, pan-Arabism, pan-Germanism, pan-Italianism); others stressed regional linguistic loyalties or the nonlinguistic ties of race or religion.

Linguists have generally sympathized with the political aspirations of ethnolinguistic groups to achieve statehood, but have simultaneously favored the language rights of marginalized or disenfranchised ethnic minorities within such states. The contemporary sociology of language has its roots in pre-war European ethnolinguistic politics, and in the political tensions that underlay the vulnerable position of linguistic minorities in the newly drawn political boundaries of post-Versailles Europe. In the 1930s and 1940s, the advocacy by nationalist linguists of the rights and autonomy of national languages and their distinct world view, as well as of historically grounded claims of the relationship between language and territory, in some cases offered support for aggressively expansionist political ideologies (Kloss, 1941; Hutton, 1999). However, internationalism and support for auxiliary international languages was also a strong feature of linguistic theorizing in the first half of the 20th century, with links to the search for a universal language of science.

Linguistics and Anticolonial Nationalism

Debates about the interrelationship of language and identity were exported to Africa and Asia via European colonialism. The rejection of classical languages (in India, Persian, Sanskrit, Arabic) and the standardization of vernacular languages was one of the central linguistic projects of modernizing colonial language politics, in tandem with the use of the colonial language. This model was laid out in Thomas Macaulay's "Minute on Indian Education" (Macaulay, 1835). Modernizing colonialism promoted hybrid systems in education, government, the armed forces, etc. using both the vernacular and the colonial languages, and within the framework of colonialism, language censuses, the rise of centralized education systems, and the fieldwork of missionary and colonial linguists, introduced Western linguistic concepts and labeling practices. As in Europe, these politicized vernacular identities put in question the authenticity of the colonial or dynastic state, and often formed the basis for anticolonial nationalism. Nationalist linguists picked up where their missionary and colonial predecessors had left off, continuing with standardizing and lexicographical projects, but now within a nationalist or nativist ideological framework. In 19th century China, Protestant missionaries

had devised writing systems for dialects and pressed for language reform at all levels (Gibson, 1902). In the 20th century, Chinese linguists and intellectuals debated a wide range of possible modernizing reforms, and saw language reform and modernization as central to the nationalist project (DeFrancis, 1950). Language reforms may support a modern egalitarian national identity, but often at the cost of a rupture with a complex (elite) textual history, as has been argued in the case of Turkish (Lewis, 2000).

In the post-war era of decolonization, sociolinguists turned to Africa and Asia to analyze the sociopolitical dilemmas of newly created states. These states were arguably more weakly rooted in a preexisting "ethnic-cultural unity" than the new nations that emerged after World War I (Fishman, 1968). However, again as in Europe, the application of a political ideology based on mother tongue or language rights was potentially both liberating for the postcolonial state and destabilizing for any hybrid polity. Einar Haugen (1906–1994) described an evolutionary process within emergent nationalism from dialect or vernacular to language (Haugen, 1966). A dialect was in effect a thwarted language, one that had failed to become the medium of an independent polity. The political problem intrinsic to this model is that the number of potential languages, and therefore nations, is unbounded, as there is no limit to the number of divisions in the linguistic continuum that can be made. The application of this (essentially northern European) model to postcolonial Africa and Asia remains problematic for the integrity of multiethnic states.

One needs to be aware of the diverse positioning of academic linguists within the political culture of the states in which they work. A professional linguist based in North America concerned with the syntax of English can evade questions of national language policy more easily than a linguist working in a postcolonial state with complex language planning problems. For example, the linguist Y. R. Chao (1892–1982) was active in the promotion of a unified national language and of a standardized Romanization system in Republican China (1912–1949). One could not write the history of linguistics in the People's Republic of China (1949 to the present) without giving national language planning and language policy a central role.

Languages as Sociopolitical Constructs

Complicating the politics of language for the linguist is doubt about the methodological and political status of the term 'language' itself. Ferdinand de Saussure's synchronic notion of *langue* can be read politically as reflecting the ideal of a polity organically integrated and conceptually united through a shared linguistic system (de Saussure, [1916] 1972). Yet linguistics also provides intellectual tools for emphasizing the inadequacy of this model, and for conceptualizing almost unlimited forms of diversity and variation, as well as offering different understandings of the linguistic unity (e.g., universal grammar) and diversity of the human species.

Linguistics has wavered between the view that human linguistic diversity is natural (Fishman, 1997) and the understanding that languages are sociopolitical constructs. The ideal of a national language that gives identity to the polity that it represents can be seen as a product of Western modernity, which when applied to other cultural contexts involves the destruction of the preexisting linguistic ecology, one which may not have involved self-awareness about discrete linguistic labels (Mühlhäusler, 1996). In the same way, the European nation state model has been seen as disrupting non-Western indigenous political ecologies. Roy Harris has characterized the notion of languages as stable systems of communication as "the language myth," which in its modern form "is a cultural product of post-Renaissance Europe" and reflects "the political psychology of nationalism, and an educational system devoted to standardizing the linguistic behaviour of pupils" (Harris, 1981: 9). To Western linguists applying the mother tongue model of European identity politics, the Chinese regional varieties were akin to the national languages of Europe (Dyer Ball, 1907). Within the national and nationalist framework of modern Chinese linguistics, there is, however, no question but that these varieties are the dialects of a single language, Chinese. But the rise of vernacular dialect/language politics in contemporary Taiwan points to the evidently political nature of these categorizations.

The view of languages as constructs can be contextualized in debates about globalization within linguistics. The nation–state has been understood as one of the pillars of modernity, and as such it is presumed to have been eroded under the impact of postmodern globalization, with the rise of hybrid forms of identity and cultural affiliation, and the emergence of the first truly global language, English. English itself can be understood either as taking on partially or wholly indigenized national forms (Indian English, Singapore English, etc.) or as an increasingly decentered language that does not respond to national and state boundaries. Nationalism, including linguistic nationalism, remains, however, a potent political force, especially following the dissolution of the Soviet Union in 1991. No doubt linguists will continue to play a complex range of roles, including those

of commentator, ideological critic, and nationalist activist.

Native Speaker

R Singh, Université de Montréal, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Although the rise of the idea of a (naïve) native speaker can be, as pointed out by Dasgupta (1998), traced as far back as the antiurbanist impulse released by German Romanticism of the 19th century, the use of the expression *native speaker* became prevalent in modern linguistics, particularly since the Chomskyan intervention in linguistics, which in perhaps its least appreciated aspect brings metropolitan linguistics back home to the West after a rather long detour to various peripheries and colonies. Although some would argue that Chomsky's ideal native speaker does not look very different from the native speaker of those who hold a more prescriptivist position, he takes the theoretical view that we are all native speakers of the steady state grammar we develop on the basis of innately specified language capacity.

Scholars concerned with what Chomsky calls E-language are, of course, preoccupied with the question: of which language? This, as Muysken (1998) points out, is not a straightforward matter for the internal language/external language (IL/EL) mapping is more often than not asymmetrical (cf. Hindi and Urdu in South Asia, which arguably represent the same IL, and Patois, Dialect, and Quechua in South America, which presumably manifest different IL's). Nor is the relationship between language competence and language use a straightforward one, for the former seems to crucially depend on the latter, as can be clearly seen in language attrition (cf. Seliger and Vago, 1991). These considerations of asymmetrical mapping and use bring social parameters and sociolinguists into the picture. A further complication is added by the so-called indigenized varieties of some European languages, particularly English (for obvious reasons behind its international spread). The debates regarding the status of these varieties, at least some of which are demonstrably fully rule-governed linguistic systems, have made it increasingly clear that both ownership and multilingualism must be taken into account in providing a more viable characterization of the notion of *native speaker.*

Earlier accounts of the notion of native speaker, such as the ones collected in Paikeday (1985) and Coulmas (1981), try to come to terms with some of the complications summarized above. However, with only a couple of exceptions, they do so with what must be seen as a monolingual/monocultural bias, remarkably clearly spelled out by Crystal (1985) and Quine (1985), and with almost no awareness of questions thrown up by the existence of varieties such as Indian and Singaporean English. The old monolingualist characterization of the concept of native speaker – as mother tongue or first language – may no longer be sufficient (cf. Pattanayak, 1981 and Harris and McGhee, 1992; among others). Token homage to multilingualism or minor adjustments to such a characterization can't solve the problem, because they tend to take a simplistic view of multilingualism.

The functionally determined distribution of the use of particular languages and the concomitant acquisition and competence in them in multilingual societies makes such accounts inadequate because neither the proficiency nor the competence of a multilingual speaker can be described in simple, additive terms – a bilingual speaker is not a simple, additive union of two monolingual speakers. The existence of indigenized varieties of English (and some other European languages) makes these accounts look even worse. It is one thing to de-emphasize or question the role of introspection in linguistics, as many of the contributors to both Paikeday (1985) and Coulmas (1981) do, but quite another to come to terms with what Coulmas (1981: 1) calls "the common reference point" for all of linguistics. Although the question of the relationship between use and the acquisition and sustenance of competence needs to be researched more thoroughly than it has been, no harm is done if the expression *native speaker* is understood as *native speaker/user,* as no one will deny that to become and to remain a native speaker of a language one must use it.

The question, as Kandiah (1998: 90) puts it, is not whether the native speaker/user exists – Paikeday's dismissal of the concept is much too cavalier – but "what we mean when we say that people know, use and view a language in a manner that allows them to see themselves as and to be recognized and accepted as native speakers/users of it." "To be recognized as" and "to be accepted as" add the dimension of ownership or proprietorship to an already complex set of parameters that must be taken into account in defining the native speaker/user. In other words, the native speaker/user is not dead, as the title of Paikeday's book suggests, but has simply been somewhat prematurely buried by some. Kandiah (1998) rightly insists that the fact that large numbers of ordinary people consciously or unconsciously assume the notion *native speaker/user* in their interactions guarantees that it captures something real. Although it is instructive to deconstruct certain construals of *native speaker/user,* not much is to be gained by discarding the concept completely. Even if

the assumption that one is naturally proficient in one's mother tongue is rejected, Paikeday's suggestion that we use "proficient user of a specified language" instead of *native speaker/user* is not productive because we need to know how to measure proficiency and who determines the norms against which such measuring will take place.

As the considerations that preoccupy most of the contributors to Paikeday (1985) – for example, mother tongue, the age at which acquisition of the language in question began, and the order of acquisition – are rendered irrelevant by the functionally distributed use of and competence in several languages in multilingual societies' the only way to avoid being sidetracked by them is to attempt a characterization grounded squarely in the reality and psycholinguistics of multilingualism. Singh (1994) offers the sort of characterization I believe is needed: "Grammatically speaking, a native speaker of a language is a person who has relatively stable and consistent grammaticality judgements, which he shares with some other speakers, regarding structures alleged to be from his language." A native speaker/user is, in other words, a speaker/user whose well-formed judgments on utterances said to be from her language are shared by her community. Only a definition of this sort can, it seems, preserve the innocent grain of truth in structuralist and generativist conceptions of the native speaker and acknowledge the considerations Kandiah rightly brings to our attention. It also exposes the oxymoronic nature of labels such as *non-native varieties of X* by making it clear that whereas one can legitimately say that native speakers of Texan English are not native speakers of Heartland Canadian English, one cannot legitimately say that native speakers of Texan English are not native speakers of English (because they do not speak Standard British or Standard Midwestern American English).

Although some of the questions thrown up by the emergence of varieties of English such as Indian and Singapore English are very important for characterizing the notion of a native speaker/user, the debates regarding the status of such varieties unfortunately tend to be almost journalistic. Consider the easily understood matter of lexical innovation and morphology, for example. The preoccupation with pedagogy and an almost complete neglect of grammar in the contemporary sense reduce most discussions of lexical innovation in such varieties to journalistic reports on exotica. It is true that Indian English, for example, has words that are peculiarly its own, but all varieties of English have words that are peculiarly their own. Although the delight of discovering words that are unknown in other, particularly standard, varieties of English is understandable, the unfortunate conclusions that are drawn from such excursions into exotica are unwarranted and seem to stem from a lack understanding of the morphology of Indian English. It is important to look carefully at the morphologically complex words in Indian English and other such varieties. Morphologically complex innovations result from an interaction between requirements of the material landscape and what grammar permits, and here these varieties do not offer much that is radically different.

The fact that *goonda* 'gangster' or *lathi* 'stick' exist only in Indian English is no more interesting than the fact that *tuque* 'a knitted cap resembling a long stocking' exists only in Canadian English. These would be notable if the peculiarity of the lexicon of Indian English could be attributed to a distinct and peculiar morphology. Such an attribution, however, seems unwarranted. Like the peculiarity of the lexica of all other varieties of English, the peculiarity of Indian English seems limited to simplexes. Hosali (1998) intended her example of *lathi-charge* 'an attack with *lathis*' to show a distinctive morphological pattern in Indian English. She notes that the distinctive feature of this morphologically complex item is "the use of a *lathi* or 'a long heavy stick made of bamboo and bound with iron.'" This explanation shows, contrary to her own suggestion, that the item is not a result of substratum- influenced morphology or of an unlicensed extension of English rules of word formation, but reflects the fact that the simplex *lathi* is a word of Indian English, a fact which is of no particular relevance to the morphology of that language. Other complex words also suggest that no such substratum influence or illegal extension is involved in the morphology of Indian English. There is, as I argue in Singh (2002), little in Indian English morphology that cannot be seen as a natural extension of patterns or rules of word-formation used or exploited in other 'native' varieties of English. Indian English certainly has simple and complex words that don't exist in these other varieties, but each one of those has simple and complex words that don't exist in the other varieties. Morphologically complex words in Indian English are, in other words, fully licensed by word-formation rules of English morphology. *Batch-mate* exists in Indian English because *class-mate* and *room-mate* exist in all varieties of English; *collectorate* exists because *directorate* exists throughout the English-speaking world.

Comparable illustrations from syntax and phonology are easy to find, but perhaps it is sufficient to point out here that there are no structural features at any level of grammatical description that characterize all non-native varieties of English to the exclusion of all native varieties. Given that most linguists

who have made serious efforts to find such features acknowledge that there aren't any (cf. Trudgill, 1995), we are fully justified in concluding that the dichotomy native variety/non-native variety cannot be structurally or grammatically sustained. And if it indeed cannot be sustained, speakers of at least the varieties that can be shown to have their own norms, such as Indian English and Singapore English, must be classified as native speakers of English by virtue of the fact that they are native speakers of their respective varieties – the fact that they are not native speakers of some other variety is irrelevant. This is, of course, consistent with the definition in Singh (1994). Although we fully recognize the importance of acceptance, recognition, and ownership, the definition itself does not have anything to say directly about them, because, as I have argued extensively, these are clearly politico-economic matters, better discussed and negotiated elsewhere (see Lele, 2005). It is perhaps counter-usage, but, fortunately, no more so than the definitions of *democracy* in English dictionaries, for example, which define it not in terms what it actually is but in terms of what it could potentially be. It can, hopefully, be used to persuade those who insist on using technical expressions somewhat arbitrarily that they should refrain from doing so.

It is at least mildly ironic that whereas the asocial tradition of linguistic or grammatical inquiry sees and characterizes the speakers of the sorts of varieties mentioned above as native speakers of these varieties, the allegedly socially responsible tradition of sociolinguistics is responsible for creating the expression *non-native variety*. The former honors its commitment to treat all viable, rule-governed systems of linguistic communication at par, but the latter seems more than willing to sacrifice the grain of innocence contained in the impulse released more than a century ago. It is the sociolinguist's intervention that adds to the understandable pedagogical dichotomy *native/non-native speaker* the unlicensed dichotomy *native/non-native variety*. Why some native speakers of English want to treat some other native speakers of English as non-native speakers is an important question, the answer to which is to be found in the political economy of the contemporary world, though sociolinguists are welcome to try to answer it. Why some English-speaking sociolinguists also want to do that is perhaps an even more important question, at least for theorizing about language and society. And in what is perhaps the final irony, the only sustainable interpretation of 'non-native variety' may well be the interpretation 'not of the land' or 'still retaining its otherness' – that is why the structuralist argument that Indian English, for example, is just as self-contained a system as RP English, for example, sounds like a threat to speakers of other Indian languages in India. That it also sounds like a threat to speakers of RP English is easy to explain – such a status is seen as a demand for a share in the cultural and political power wielded by the native speakers of English in the inner circle inhabited by RP English speakers. This interpretation is, at any rate, not the one that the creators of the expression *non-native variety* and the promoters of a demonstrably unwarranted use of *non-native speaker* in scientific discourse have in mind. It is not available to them because the non-nativeness they see in or want to confer on varieties such as Indian English and Singaporean English resides in their view, as they make repeatedly clear, in the Indianness or Singaporeanness of these varieties. It can be invoked only by those who, like Dasgupta (1993), believe that the non-nativeness of these varieties (from an indigenous perspective) resides instead in their Englishness.

Natural Kind Terms

S Gross, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Natural kind terms denote, or purport to denote, natural kinds – for example, physical, chemical, and biological kinds. They are of particular interest to philosophers concerned with what enables us to think and talk about natural kinds. According to *descriptivism*, the denotation of natural kind terms is determined by an associated description. According to *causal theories*, the denotation is determined by language users' causal interactions with exemplars. Hybrid views are also espoused. These positions parallel those taken on the denotation of proper names (cf. Stanley, 1997; *see* **Proper Names: Semantic Aspects** and **Proper Names: Philosophical Aspects**).

Debates about natural kind terms carry implications for a variety of philosophical issues. Causal theories, for example, are *prima facie* in tension with a methodological individualism that assumes that cognitive properties – including the semantic properties of an individual's terms – are determined by properties intrinsic to the individual (cf. Burge, 1979). Discussions of natural kind terms also intersect with debates in cognitive psychology concerning tacit essentialism (cf. Gelman, 2003) and with discussions in the philosophy of science concerning the bases for successful inductive generalization (cf. Kornblith, 1993).

What Are Natural Kind Terms?

Human first languages do not syntactically or morphologically mark natural kind terms as such. Natural kind terms are distinguished solely by the kind of kinds they purport to denote. What then are natural kinds? The core idea is that they are object groupings that reflect real distinctions in nature – in particular, distinctions that play an explanatory role in (accurate) scientific theories. Natural kinds are contrasted with arbitrary groupings of objects whose behavior cannot be explained by shared fundamental properties – for example, the kind comprising Plato's left ear, the natural numbers, and the shoes owned by current heads-of-state. Natural kinds are also contrasted with conventional groupings that reflect practical human concerns, such as the citizens of Pennsylvania. Relatedly, they are contrasted with artifactual kinds – objects grouped together in virtue of our intending them to fulfill certain functions, such as tables. Natural kind terms thus arguably include 'gold,' 'tiger,' and 'H_2O'; but not 'keys' or 'gorks' (where it is hereby stipulated that something is a gork if and only if it is Plato's left ear, a natural number, or a shoe owned by a current head-of-state).

This basic characterization leaves much room for disagreement about just which terms are natural kind terms. First, it admits adjectives – at least those that denote groupings that reflect real distinctions in nature (perhaps 'red' but not 'cultural' – cf. Kripke, 1972). But on some views, not all groupings are kinds, and so not all terms for them are kind terms. Many restrict kind terms to nouns or noun phrases that admit a generic reading, accept kind-level predicates like 'are widespread,' and are associated with criteria of individuation. These terms may be either mass or count nouns (cf. Carlson, 1991).

Second, there are disagreements about various further theses concerning natural kinds and, as a result, disagreements about which kind terms are natural kind terms. Some maintain, for example, that instances of a natural kind share an unchanging essence, that natural kinds fall into a non-cross-classifying hierarchy, or that natural kinds have no borderline instances.

Natural Kind Terms

S Gross, University of Pennsylvania, Philadelphia, PA, USA

Natural kind terms denote, or purport to denote, natural kinds – for example, physical, chemical, and biological kinds. They are of particular interest to philosophers concerned with what enables us to think and talk about natural kinds. According to *descriptivism*, the denotation of natural kind terms is determined by an associated description. According to *causal theories*, the denotation is determined by language users' causal interactions with exemplars. Hybrid views are also espoused. These positions parallel those taken on the denotation of proper names (cf. Stanley, 1997; *see* **Proper Names: Semantic Aspects** and **Proper Names: Philosophical Aspects**).

Debates about natural kind terms carry implications for a variety of philosophical issues. Causal theories, for example, are *prima facie* in tension with a methodological individualism that assumes that cognitive properties – including the semantic properties of an individual's terms – are determined by properties intrinsic to the individual (cf. Burge, 1979). Discussions of natural kind terms also intersect with debates in cognitive psychology concerning tacit essentialism (cf. Gelman, 2003) and with discussions in the philosophy of science concerning the bases for successful inductive generalization (cf. Kornblith, 1993).

What Are Natural Kind Terms?

Human first languages do not syntactically or morphologically mark natural kind terms as such. Natural kind terms are distinguished solely by the kind of kinds they purport to denote. What then are natural kinds? The core idea is that they are object groupings that reflect real distinctions in nature – in particular, distinctions that play an explanatory role in (accurate) scientific theories. Natural kinds are contrasted with arbitrary groupings of objects whose behavior cannot be explained by shared fundamental properties – for example, the kind comprising Plato's left ear, the natural numbers, and the shoes owned by current heads-of-state. Natural kinds are also contrasted with conventional groupings that reflect practical human concerns, such as the citizens of Pennsylvania. Relatedly, they are contrasted with artifactual kinds – objects grouped together in virtue of our intending them to fulfill certain functions, such as tables. Natural kind terms thus arguably include 'gold,' 'tiger,' and 'H_2O'; but not 'keys' or 'gorks' (where it is hereby stipulated that something is a gork if and only if it is Plato's left ear, a natural number, or a shoe owned by a current head-of-state).

This basic characterization leaves much room for disagreement about just which terms are natural kind terms. First, it admits adjectives – at least those that denote groupings that reflect real distinctions in nature (perhaps 'red' but not 'cultural' – cf. Kripke, 1972). But on some views, not all groupings are kinds, and so not all terms for them are kind terms. Many restrict kind terms to nouns or noun phrases that admit a generic reading, accept kind-level predicates like 'are widespread,' and are associated with criteria of individuation. These terms may be either mass or count nouns (cf. Carlson, 1991).

Second, there are disagreements about various further theses concerning natural kinds and, as a result, disagreements about which kind terms are natural kind terms. Some maintain, for example, that instances of a natural kind share an unchanging essence, that natural kinds fall into a non-cross-classifying hierarchy, or that natural kinds have no borderline instances.

On such bases, they argue against the inclusion of various candidate kinds – and thus against the inclusion of various candidate kind *terms*. Debates concerning biological species and terms for them are a prominent example (cf. Dupré, 1981; LaPorte, 2004). (Philosophers debate many other issues concerning natural kinds, not all of which affect the classification of natural kind *terms*. For example, they disagree about whether natural kinds have reality independent of our categorizations and about what sorts of entities they are: sets, properties, complex individuals, or something *sui generis*.)

Third, the use of many putative kind terms seems sensitive to human interests. It may seem that we have discovered that the denotation of 'water' is shared by 'H_2O.' But the uses of 'water' and of 'H_2O' are sensitive to amounts and kinds of impurities in differing ways. We would hesitate to call tea 'water' but not the stuff flowing in a river, even though the latter might have more impurities vis-à-vis H_2O than the former. However, neither tea nor a contaminated river is H_2O. Some conclude that 'water' is not a natural kind term, while others argue that such phenomena can be explained pragmatically (cf. Malt, 1994; Braisby *et al*., 1996; Abbott, 1997).

The Semantics of Natural Kind Terms: Descriptivism

We may distinguish three questions concerning the semantics of natural kind terms:

1. the *property* question: what are the semantic properties of natural kind terms?
2. the *foundational* question: in virtue of what do natural kind terms have these semantic properties?
3. the *competence* question: what is required for a speaker to grasp the semantic properties of natural kind terms?

The past 30 years of debate have been shaped to a large extent by Kripke's (1972) and Putnam's (1975) attacks on *descriptivism*. Classic descriptivism maintains three theses corresponding to these three questions. According to *property descriptivism*, the semantic properties of a natural kind term are those of some definite description. According to *foundational descriptivism*, a natural kind term has a particular semantic property – its denotation – in virtue of its relation to such a description. According to *competence descriptivism*, a speaker understands a term in virtue of associating it, explicitly or tacitly, with such a description.

Forms of descriptivism can be further articulated in various ways. For example, John Locke (1979: Book III, Chapter VI) – a *locus classicus* of descriptivism – in effect required that the relevant descriptions be constructed from observational terms. This is because his descriptivism is in service to his developmental and epistemological empiricism, according to which mental states arise from and are justified by experience. Locke distinguished the 'real essence' and the 'nominal essence' of substances, such as gold. The real essence is what makes gold what it is. Locke was pessimistic that we could ever discover a substance's real essence. The nominal essence is the list of observable properties that a speaker associates with the term for this substance. Locke held that the term 'gold' signifies an "abstract idea" composed of ideas of these observable properties (shiny, yellow, malleable, etc.). A natural gloss is that the content of a natural kind term like 'gold' is given by and identical to an observational description such as 'the stuff that's shiny, yellow, malleable, etc.,' and a speaker grasps that this is the term's content in virtue of taking that description to define it.

Against Descriptivism

Descriptivism is a natural view since such features clearly play a role in categorization. But Kripke and Putnam raised a host of objections aimed at separating how people categorize things from what determines the denotation in fact possessed by their terms.

First, there are *modal* objections. Consider 'gold' and a candidate Lockean description. Arguably, the sentence 'gold is gold' expresses a necessary truth – as does, on at least one reading, 'the shiny, yellow (etc.) stuff is the shiny, yellow (etc.) stuff.' But 'gold is the shiny, yellow (etc.) stuff' does not. For it is metaphysically possible both that there be stuff that possesses those observable properties but differs from gold in some fundamental way and that there be gold lacking some one of those properties. Relatedly, 'it's necessary that gold is gold' expresses a truth, but 'it's necessary that gold is shiny, yellow, etc.' does not. (It is thus often maintained that natural kind terms are rigid designators [*see* **Rigid Designation**], although how best to extend the concept beyond proper names is not obvious and depends on what one takes a kind to be; cf. Soames, 2002.)

A second, *epistemic* objection is that the descriptions associated with natural kind terms may be false without affecting the natural kind term's denotation. Suppose that I falsely believe that tigers are the fastest cat and that this is a fundamental, defining characteristic of tigers. It does not follow that, when I use the word 'tiger,' I in fact denote cheetahs. More generally, one might reject a view according to

which, as scientists revise their core beliefs in the light of new research, the denotation of their terms changes, so that scientists adopting different theories become communicatively isolated behind incommensurable vocabulary.

Finally, the *absence* objection points out that speakers competent in the use of a natural kind term often do not associate any particular description with it at all – or at least none that the speakers themselves would consider especially relevant semantically or that would uniquely pick out the natural kind at issue. Putnam (1975) notes that what he happens to know of beeches basically coincides with what he happens to know of elms, so he has available no descriptions that would account for the distinct denotations of 'beech' and 'elm.' Further, even if there are descriptions that uniquely pick out these kinds, it is far from obvious that they play any role in a speaker's cognitive economy.

Causal Theories

Rejecting descriptivism allows one to recognize the possibility of misalignment between what one's terms are about and how one conceives of them. But, if not one's conception, what determines the denotation of natural kinds terms? Causal theories deriving from Kripke (1972) and Putnam (1975) endorse a two-part account of the foundational semantics of natural kind terms: the denotation of natural kind terms is fixed by appropriate causal interaction with instances of the kind and can be socially transmitted to others by patterns of linguistic deference. A natural kind term is introduced with an intention – or comes to be used with an intention – that it denote stuff relevantly similar in underlying structure to *stuff like that*. What fixes the denotation is thus something like a Lockean real essence. 'Gold' denotes, not the stuff that shares various observable properties, but rather the stuff that has some fundamental properties responsible for the observable ones, whatever those fundamental properties might be. People not privy to samples of such stuff intend to use the term as do those who are. The denotation of 'beech' in Putnam's idiolect, for example, is fixed by the fundamental properties of the samples with which those to whom he defers have interacted. Scientific inquiry enables us to learn about these fundamental properties, but linguistic competence does not require – indeed, arguably helps make possible – such knowledge.

On such a view, what semantic properties a natural kind term has are in part determined by features external to speakers – by the (perhaps unknown) underlying nature of the ostended stuff and by features of one's linguistic community. Kripke's and Putnam's foundational semantics for natural kind terms thus supports *linguistic semantic externalism* – the thesis that the semantic properties of one's terms do not supervene on one's intrinsic states. A particularly vivid illustration is provided by Putnam's 'Twin Earth' thought experiment. Suppose that there is another planet just like ours except that, in place of water (H_2O), its lakes, oceans, swimming pools, etc., are filled with XYZ, a liquid superficially similar to water in appearance, taste, odor, etc., but with a different chemical microstructure. Since XYZ is not H_2O, it is not water but rather something that merely resembles water. Now, suppose Oscar is a denizen of Earth, and Twin Oscar is his counterpart on Twin Earth – an exact duplicate with respect to intrinsic properties. Out of Oscar's mouth, 'water' denotes water (H_2O), but not XYZ. Were it pointed out to Oscar that the liquid he just referred to as 'water' was in fact made up of completely different stuff, he would admit that he'd been misled by its superficial resemblance to water. Out of Twin Oscar's mouth, 'water' denotes XYZ (that is, what *they* call 'water' on Twin Earth), but not water – for parallel reasons. But Oscar and Twin Oscar are intrinsically identical. Therefore, their words' semantic properties are a function, not just of their intrinsic states, but also of external factors. Such externalism stands in sharp contrast to, for example, Chomsky's internalist conception of language (*see* **E-Language versus I-Language**).

Descriptivism Redux

Descriptivists have defended themselves both by replying to Kripke's and Putnam's objections and by raising problems for causal theories.

In reply to the *modal* argument, one finds four objections, presented here in increasing order of concessiveness. Some reject the very idea of metaphysical modalities. Others reject the intuitions behind the particular modal claims made, sometimes adding that such intuitions are sensitive to framing effects (and might not be cross-culturally robust – cf. Machery *et al.*, 2004). Then there are those who deny that critics have considered the *right* descriptions: if 'gold' is associated with a *rigidified* description such as 'what's actually the most precious yellow metal,' the modal argument is blocked. Finally, some point out that the argument, if successful, applies only against *property* descriptivism and so does not yet pose a problem for strictly *foundational* descriptivists.

In reply to the *epistemic* objection, a descriptivist might likewise complain that causal theorists focus on the wrong descriptions. There must be *some*

accurate description that can be associated with the natural kind term. For instance, the relevant description could be constructed from the causal theorist's account of the determination of natural kind terms' denotation: 'the stuff that (actually) stands in such-and-such causal relations to users of the term K.' It may be objected that speakers can be competent in the use of natural kind terms despite not associating them with such theoretically sophisticated descriptions. We return to this sort of objection presently. But there are also less theoretically sophisticated candidate descriptions, such as 'the stuff that's (actually) relevantly like *this* stuff, or the stuff others have talked about' (so long as there is no bar on demonstratives), or on some views 'the stuff that's called water in this language' (cf. Haas-Spohn, 1997).

In reply to the *absence* objection, a descriptivist might posit tacit knowledge of the description's bearing on the natural kind term. That is, the descriptivist might hypothesize that the mind or brain associates natural kind terms with such descriptions, even though a speaker is not necessarily aware of this. Alternatively, a descriptivist might argue that such descriptions can play the role required by *property* and/or *foundational* descriptivism despite speakers' ignorance of them. Rather than positing tacit knowledge, the descriptivist might then abandon *competence* descriptivism altogether. This might appeal in particular to those who deny that a semantic theory must also play a role in an account of semantic competence. According to such theorists, the task of semantics is to characterize the semantic properties of expressions, not to explain how speakers grasp those properties (cf. Katz, 2004).

In addition to replying to causal theorists' objections, descriptivists emphasize that causal theories face *prima facie* problems of their own. First, it is not obvious how causal theories should accommodate apparently denotationless natural kind terms such as 'phlogiston' and 'unicorn' (*see* **Empty Names**). These terms are not synonymous. But it is unclear how a causal theorist can distinguish them semantically, since the theorist cannot appeal to a difference in denotation. Descriptivists face no problem here, since they can associate such terms with nonsynonymous descriptions ('the stuff flammable material gives off in combustion'; 'the horse-like mammal with a magical horn').

Moreover, causal theorists face the *prima facie* problem that, on their view, 'phlogiston' is not a denotationless term after all, since it was introduced via interaction with instances of combustion and thus arguably denotes *oxygen*, the stuff in fact responsible for the observed behavior. Unless they can resist this consequence, causal theorists would be committed to a history of science according to which phlogiston theorists were correct that phlogiston exists but simply wrong that it comes from the flammable material.

Finally, an object can be an instance of various natural kinds. If my use of 'gold' is associated with exemplars that are not only Au but also all instances of a particular isotope, what determines to which kind my term refers? Perhaps indeed the term should denote *metals*. This is an instance of the *qua*-problem (anticipated by Locke – cf. Stanford, 1998): it is unclear of what kinds the instances are exemplars, in particular whether we are to consider the instance *qua* gold, *qua* metal, *qua* a certain isotope, etc. Here too it can seem that the foundational semantics requires a constraining descriptive component.

Hybrid Views

In part for these reasons, some have developed hybrid views. There are two not mutually exclusive ways one can combine a moderate descriptivism with a causal theory – both of which have antecedents in Putnam (1975). First, some defend a limited *property* descriptivism while abandoning the claim that the denotation of natural kind terms is determined solely by such descriptions. The idea is that among the semantic properties of a natural kind term is an associated description (or a meaning with description-like content), even though the denotation is not determined by this description and might not align with its extension. Second, some maintain that a natural kind term's denotation is determined by causal relations to exemplars as constrained by some descriptively characterized requirement. It is not sufficient to say that a natural kind term denotes *stuff like that*: it must be stuff that is *relevantly similar* to the exemplar in ways that require at least some descriptive elaboration (cf. Stanford and Kitcher, 2000).

Neodescriptivists have attempted to absorb the insights of causal theories in other ways as well. We have already noted that one might include rigidifying and/or demonstrative expressions in the descriptions. In addition, some theorists distinguish two dimensions of semantic content: a description-like first intension and a second intension that, in the case of natural kind terms, is a function of the first intension and the actual environment of the speaker. The first intension determines a classically descriptivist extension. The second intension, however, does not determine an extension on its own at all; it constrains an extension that is in part determined by how the world in fact is (cf. Chalmers, 2002; *see* **Two-Dimensional Semantics**).

Communicating More Effectively with Computers

As technology has progressed to the point where computing hardware is at its most affordable, one can readily argue that the limiting factor in the usability of computers is the usability of the interface. At the onset of interactive computing, the ability to manipulate the data and programs resident on a computer was restricted to individuals able to master the very rigid syntax and vocabulary of command line interfaces. Consider the following scenario:

> Given a file of data containing test results, calculate the relevant statistics about each person and display and save a table of results in sorted order based on average.

A command line to complete this task might look like the following:

```
stats < data.txt | sort –k 3,3n > results.txt ; lpr
  results.txt
```

where *stats* is the program for calculating statistics, *data.txt* is the input file, and *results.txt* will be the output file.

Communicating More Effectively with Computers

As technology has progressed to the point where computing hardware is at its most affordable, one can readily argue that the limiting factor in the usability of computers is the usability of the interface. At the onset of interactive computing, the ability to manipulate the data and programs resident on a computer was restricted to individuals able to master the very rigid syntax and vocabulary of command line interfaces. Consider the following scenario:

> Given a file of data containing test results, calculate the relevant statistics about each person and display and save a table of results in sorted order based on average.

A command line to complete this task might look like the following:

```
stats < data.txt | sort –k 3,3n > results.txt ; lpr
  results.txt
```

where *stats* is the program for calculating statistics, *data.txt* is the input file, and *results.txt* will be the output file.

Alternatively, if one wanted to produce some type of graph or bar chart, the sort command would have to be replaced with the name of the appropriate program and another complicated set of flags and arguments (such as *–k 3,3n*) would likely need to be specified to produce the proper behavior.

An advance in interface usability is the now ubiquitous graphical user interface (GUI). The GUI primarily relies on the point-and-click control of a mouse to select files, data in files, and programs. With a GUI, the sample problem might be handled by completion of the following tasks:

- Select the desired program (*stats*) based on location of its associated icon.
- Select the run action from a hierarchical set of menus.
- Specify the input file *data.txt* in a dialog box.
- Reorder the displayed output by clicking on the appropriate column header once or twice.
- Select the 'save as' action to store the results into *results.txt*.
- Select the print menu action and perhaps click on a few more buttons and options to generate the desired output.

With a GUI, the graph or bar chart would likely require other menu selections within the same program. Although the GUI has made interaction with computers more accessible to a greater number of people, it restricts users to a 'select and use' mode of communication and problem solving, requires users to maintain a specialized cognitive model of selection ('when do I left-click' vs. 'when do I right-click'), and requires users to have special knowledge about the location and organization of menus and icons that may vary from application to application and machine to machine.

Now consider the following alternative – a natural language interface (NLI) that might allow the user to specify the necessary actions for our sample scenario as follows:

> "I need stats run for the skills tests. Please sort them by average and display and save them into a file."

No specialized knowledge about communication is required by the user. The specification could just as easily have been provided to a human assistant. A NLI can allow people to use all the communicative power of language they already possess rather than be forced into an unnatural and limiting mode of communication such as a GUI.

This article provides an overview of the utility of various areas of study in natural language processing (NLP) (*see* **Natural Language Processing: Overview**) for constructing effective NLIs to computer applications. After discussing technical challenges in constructing NLIs, this article describes approaches to meeting these challenges and concludes with a discussion of representative NLIs that illustrate past, present, and future trends in NLI research and development.

NLI Complexity and Limitations

NLIs are subject to most if not all of the technical challenges studied by researchers investigating fundamental problems in natural language understanding (*see* **Natural Language Understanding, Automatic**) at both the utterance and discourse level. However, since NLIs are grounded within the specific domain of a computer application, the required breadth of linguistic coverage is not as large as it could be, but usually it is broad enough to lead to potential complications such as the ones discussed next.

Contextual Subtlety of Meaning and Ambiguity

Consider a NLI to an in-car navigational system that helps provide directions to the driver of an automobile. Suppose the user says, "I need to get to the airport quickly." Suppose also that the driver is somewhere in the vicinity of New York City, where there are three major airports. Without confirmation, the system could begin directing the driver to the wrong airport. An appropriate follow-up response could be, "Which airport, LaGuardia, JFK, or Newark?"

Assuming that the referential ambiguity of *the airport* is resolved, the interpretation of *quickly* is not clear-cut either. Some possible parameters that the navigational application might require in order to produce a proper response include the following:

- Exactly how quick? The possibly quickest route might also have a higher risk for traffic delays.
- The reason for getting there quickly. There is a major difference in going to the airport to catch a flight and going to the airport to pick someone up. In many applications, it is important for the system to understand the underlying user goals.

Now consider a slight variation of the same situation, in which the NLI is to a telephone-based travel assistant and the user is now looking for suggestions that involve public transportation, such as subways, buses, and taxis.

> "I want to get to the airport quickly and cheaply."

Depending on the relative constraints of time and money, various suggestions are possible. The interface must be capable of engaging the user in extended dialog that takes context and domain knowledge into account in order to properly advise the user.

Diversity of Expression

Consider the following paraphrases of "I want to get to the airport quickly":

What's a [fast|quick|short] route to the airport?
How do I get to the airport as [fast|quickly] as possible?
Can you tell me a [fast|quick|short] route to the airport?
It would be nice to get to the airport quickly.

All these statements are reasonable within the context of a conversation between two people. Unfortunately, not all of them are likely to be reasonable for a NLI. Due to resource constraints in the development process, designers of NLIs invariably must take steps to constrain the allowed language. Common strategies include the following:

1. Constrain syntax and vocabulary of system responses to the allowed forms of input. Users will tend to adopt the language forms they perceive the system to be using.
2. Structure responses to constrain user input choices. This presumes that users will attempt to be cooperative. Compare the following two choices for the initial system statement for a NLI for a travel assistant:

   "What are your travel plans?"
   "Tell me your destination city."

   The second response naturally constrains the set of maximally cooperative user responses.
3. Provide feedback that enables users to track the progress of the interaction to ensure that proper understanding is occurring. Consider the following sample:

   System: Tell me your destination city
   User: Nashville.
   System: Your destination is Asheville. Tell me your departure city
   User: No, I said Nashville.
   System: Correction, your destination is Nashville. Tell me your departure city.

   Without feedback, the system error might not be detected until several statements later. Note that the previous example would occur in a speech-based interface rather than a typing interface. However, a NLI that uses typed text for input tends to allow a wider range of syntax and vocabulary as well as encourages users to communicate via longer responses. Techniques for handling these issues associated with typed input are discussed later when a description of the Why2-Atlas physics tutor is provided.

To summarize, NLIs enable much greater expressiveness for users than GUIs, but steps must be taken to constrain the level of expressiveness so that the NLI is technically feasible. The next section examines key development principles of NLIs and presents a generic architecture for a NLI that will form the basis of our discussion of actual NLIs.

NLI Design Principles

In this section, some key principles for NLI development are discussed. Examples are drawn from the author's experience in developing a system called the Circuit Fix-It Shop (Smith, 1995).

Principle 1: Acquire data on language use for the application domain. It is absolutely crucial to collect data on language use for the problem domain for which the NLI is being constructed. The most common sources of data are samples of human–human conversation and the use of Wizard-of-Oz (WOZ) simulations of human–computer interaction. In a pure WOZ simulation (Fraser and Gilbert, 1991), the user is led to believe that he or she is interacting with an actual computer system, but in reality a human is processing the user's input and controlling the prototype system responses. WOZ simulations tend to require extra time initially to develop, but they can potentially provide more accurate data on what users may actually attempt with a real NLI.

Principle 2: Develop semantic representations for the meaning of user input that are consistent with the semantic representation used in the application domain. Consider the following two utterances and possible meaning representations:

"The switch is not on."
assertion (switch, position, on, false).
"The switch is off."
assertion (switch, position, off, true).

The utterances have the same meaning but their basic representation looks different. This can be further compounded if we consider 'up' and 'down' to be synonyms for 'on' and 'off' in this domain. A decision must be made about the form of canonical representations and consistently used. This is, of course, easier to achieve when the NLI designer is the same person or group as the application domain designer, but this is not always the case, especially in nonresearch-oriented NLIs in which the application software is likely to predate the NLI. This problem can become very challenging in an NLI to a database in which many synonyms and paraphrases for entities and relationships may be present in the NLI.

This same principle applies to the natural language generation (NLG) component. This component must be able to take the representations for responses that come from the application program and produce appropriate natural language responses.

Principle 3: Decide early the level of separation to be maintained between language processing components of the NLI and the application's domain reasoning components. Greater reusability is possible if the NLI software is kept completely separate from the application domain software, but it is not always easy to do. The issue becomes particularly complex when choices of meaning representations are made. Consider the following statements about a numeric electronic display called an LED:

1. The LED is displaying a flashing five.
2. The LED is not displaying a flashing five.
3. The LED is displaying only a flashing five.

The simplest way to keep a separation is to have the NLI produce parse trees for the sentence structure and then send them to a hybrid component that produces a meaning representation usable by the domain reasoning component. The complication arises when domain context is needed to get a complete and accurate meaning representation. Suppose for example, the desired LED display is an alternately flashing five and seven. Given that context, the domain-specific meaning for each utterance would be the following

1. The seven may or may not be displaying with the flashing five.
2. The five may be displaying without flashing (or not displaying at all).
3. The specification is reasonably unambiguous.

When system designers are constrained by development time, it is convenient to have the Natural Language Understanding (NLU) component parse the user response using a semantic grammar (Jurafsky and Martin, 2000) that translates the input directly into a domain-usable representation. In such cases, the opportunity for portability and reusability is normally sacrificed. It is important to take this trade-off into consideration early in the development process.

Figure 1 shows a generic architecture for an NLI to some type of functional application (such as a database manager). This diagram is not meant to imply that only one design is possible, but it is meant to describe the primary required components of an interface that will be present in some form in all NLIs (sometimes the response component may not use natural language). Users can provide input to the interface through a variety of devices, primarily keyboard and microphone for the NL text/speech, but input may be augmented via devices designed to capture aspects of body language that people also use in face-to-face communication (e.g., gesture and eye gaze).

Figure 1 Generic architecture for a natural language interface.

Once the input signal is acquired, it will be transmitted to the NLU component for analysis. The NLU component may optionally need to interface with domain-specific information in order to complete its task.

In addition, the NLU component may need to communicate with the interaction manager (IM) as part of the understanding process. Generically, we consider the IM to be all components of the NLI that maintain information about the ongoing interaction. The most common component of the IM would be a dialog manager and associated components designed to track contextual information.

Once the understanding process is complete and a semantic representation of the user input is created,

the IM must take the user input and, in conjunction with its knowledge about the interaction and relevant information provided by the domain-processing component (e.g., the content for a response to a user query), formulate a response and send the result to the NLG component. This component will then produce an appropriate response involving NL text and possibly other output forms (e.g., graphical) and transmit the result to output devices such as a monitor, speech synthesizer, or printer.

The following section describes how several application NLIs were designed. How each interface implements the different components in the diagram and handles the key design principles previously described is the focus of the presentation.

Representative NLIs

Text-Based Interfaces

A classic early example of a research system for studying issues in developing NLIs is the Berkeley UNIX Consultant (UC) (Wilensky *et al.*, 1988). The system takes as input typed statements that specify aspects of UNIX about which a user wants to know and produces natural language responses. For instance, suppose a user wishes to remove a directory. Any of the following forms of input would be acceptable:

"I want to delete a directory."
"I want to remove a directory."
"What's the best way to delete a directory?"

In all cases the response would be the following:

"use rmdir. For example, to delete the directory named foo, type 'rmdir foo'."

The system carries out the NLU process via a two-step mechanism. The first step produces a semantic representation of what is termed the 'primal content' of an utterance. This idea is related to the notion of literal meaning, but it can be more abstract than that. For example, in representing the meaning of prepositions, the word *on* can function in various ways (e.g., "The dog is on the chair" vs. "The picture is on the wall"). However, in a primal content representation *on* is considered to have the same usage in both (i.e., it indicates a support relationship). In the second step, a more domain-specific representation that is termed the 'actual content' is produced.

Once the NLU processes are complete, domain processing carries out goal analysis, user modeling, and domain planning. The IM takes the inferred user goals (e.g., learning how to delete a directory) and normally will just specify that the NLG components produce an appropriate answer (e.g., telling the user how to delete a directory), but it can also check to ensure that the user's goals are not malicious. However, it is not capable of managing extended dialog about a topic. It manages the interaction in terms of user/system response pairs.

An example of a text-based interface that illustrates the advance in core technologies of NLP to create more sophisticated NLIs is the Why2-Atlas physics tutor (VanLehn *et al.*, 2002). The system teaches qualitative physics by having students write paragraphs explaining simple mechanical phenomena. The explanations are translated into proofs that are then analyzed for correctness. Here is a sample interaction (transcript courtesy of Pamela Jordan):

System: Suppose a man is in a free-falling elevator and is holding his keys motionless right in front of his face. He then lets go. What will be the position of the keys relative to the man's face as time passes? Explain.

Student: The keys should remain in a constant relation to the man's face. Both objects will be in a state of free-fall, and the force of air-resistance should be negligible in an enclosed elevator, so the keys, and the man's face, which are falling and accelerating at the same speed, should remain in the same relation.

System: You have answered the problem correctly except that what you have in your essay is not a sufficient explanation. Before the release, what is the relationship between the man's velocity and the keys' velocity?

Student: equal.

System: Uh huh. If gravity is the only force acting on an object, will it be moving or staying still?

Student: moving.

System: Good. Not only are the person, keys, and elevator moving, they have only gravitational forces acting on them. When an object is falling and has only gravitational force on it, it is said to be in what?

Student: normal force state.

System: Well . . . it's said to be 'in freefall.' Thus, after the release the only force on the keys and man is the downward force of earth's gravity, so they are in freefall. What force acts on all objects within close proximity to earth?

Student: the gravitational pull of the earth.

System: Yes. Besides the earth's gravitational force, are there any other forces acting on the person, keys, and elevator after the release?

Student: no, perhaps air resistance on the elevator.

System: Good. Thus, keep in mind that after the release, the only force on the person, keys, and elevator is the force of gravity.

For Why2-Atlas, the NLU is separated into two components, the sentence-level understanding (SLU) component and the discourse-level understanding (DLU) component. The SLU parses each sentence in the student's response and produces a set of logical propositions to represent the meaning of a sentence. It consists of a lexical preprocessor, parser, repair module, and statistical analyzer. The lexical preprocessor will perform spelling correction and stripping of prefixes and suffixes to produce root forms of words. The parser then does both the syntactic analysis and the construction of the logical form. It handles ungrammatical input through a variety of techniques, including skipping words, inserting missing syntactic categories, and possibly relaxation of grammatical constraints. If an excessive number of analyses is produced, statistical information about word root frequencies and grammatical analyses is used to determine the most likely parse. If the parser cannot produce a complete analysis, its partial results are passed to the repair module. If this module also fails, then statistical approaches (*see* **Parsing: Statistical Methods**) are used, including latent semantic analysis (Graesser *et al.*, 2000).

The DLU takes the collection of logical forms produced by the SLU and constructs an explanation in the form of a proof using abductive reasoning (i.e., if $P \Rightarrow Q$, and we know Q, then hypothesize P). After the proof is constructed, the DPC, a tutorial strategist, analyzes the proof to find flaws. Each flaw that is found is associated with a tutorial goal to have the student remedy the flaw in the explanation. The goals are prioritized and sent to the IM, which then sends appropriate specifications to the NLG component for construction of a response. The IM will also insert transitions as each flaw is remedied (e.g., "Good. Not only are the person, keys, and elevator moving, they have only gravitational forces acting on them . . . .").

Recent work with this system involves the use of a speech interface ITSPOKE (Litman and Silliman, 2004) for engaging the student in the follow-up interaction after the initial explanation has been typed, submitted, and analyzed. In general, speech has become a prevalent input device for NLIs; consequently, the focus of the remaining NLIs to be discussed is on those for which speech is the primary input device.

Speech-Based Interfaces

Robust Language Analysis Depending on the domain, one key factor in the construction of speech-based NLIs that must be handled is that traditional NLU strategies based on the assumption that the input is grammatical are not likely to succeed. This is due to the nature of human speech and the accuracy limitation of speech recognition technology. A system that successfully demonstrates the use of alternative strategies for NLU is the "How May I Help You" system of AT&T (Gorin *et al.*, 2002). The purpose of this system is to allow users to avoid the use of frustrating menu systems for obtaining customer service. A sample interaction is shown in the following dialog excerpt from Gorin *et al.*:

Machine: AT&T. How may I help you?
User: I have a question about my June bill.
Machine: Okay, what is your question?
User: There's a call to Tallahassee, but I don't know anyone there.
Machine: I can help you with that. Are you calling from your home phone?
User: I'm calling from my house.
Machine: Please hold on while I transfer your call.

The idea of the system is to direct user requests more quickly and accurately to the correct service provider. In fact, the authors report greater than 90% success, which represents an improvement on customers' ability to select and navigate through the alternative of hierarchical menus.

Once the word recognition process is complete, the system attempts to find phrases within the user response that are meaningful, where a mathematical measure is used to estimate meaningfulness. Furthermore, information must be used from the IM as the language model changes depending on the state of the dialog. That is, once an initial context has been established (e.g., "I have a question about my June bill"), the next response to the system query will be based on a different language model than the response to "How may I help you?"

Architecturally, this part of NLU is done by the system's speech recognition component, and the NLU component focuses on classifying the type of call the user is making. The IM decides if confirmation and clarification are required as part of the system's response and also decides if additional information is needed in order to properly route the call. It interacts with the DPC that provides a hierarchical description of operator services.

A contrasting approach that is also a commercial phone application is reported in Dybkjær and Dybkjær (2004). Their system responds to frequently asked questions for employees about holiday benefits. The system combines the use of menus with natural language. For a detailed discussion of design issues for speech interfaces (*see* **Speech Interface Design**).

NLIs That Focus on Dialog Management As technological advances have occurred in NLU and NLG, and speech recognition, although still imperfect, has

become usable, many researchers have built NLIs in which the focus has been on enhancing conversational capabilities of systems through the development of more sophisticated IMs (commonly referred to as dialog or discourse managers in specific systems). Two examples of this type of NLI work are the Carnegie Mellon Communicator System (Rudnicky *et al.*, 1999) and the Paco tutorial agent (Rickel *et al.*, 2002).

The Carnegie Mellon Communicator agent is a speech-based NLI that allows users to create travel itineraries that involve multileg airplane trips as well as hotel and car reservations. For speech recognition, NLU, and NLG components, it uses preexisting modules and techniques, sometimes with slight modifications based on domain language modeling. The IM is designed to be domain independent by creating an interpreter that can use a task-dependent script that is provided as part of the DPC. The script provides an overall guide for the structure of the interaction but does not rigidly specify a fixed order for the interaction.

The Paco tutorial agent makes use of the Collagen software system (Rich *et al.*, 2001) for managing extended collaborative interactions. One implemented instructional domain is the operation of a gas turbine engine that propels a ship. An excerpt of a sample interaction from Rickel *et al* (2002) is given below.

Student: "What next?"
Paco: (pointing) "Press the on button on engine one."
Student: presses the on button on engine one.
Paco: "Good."
Student: "I think I should set the throttle speed."
Paco: "Right."
Student: "What should the speed be?"
Paco: "The speed should be stop."
Student: sets the throttle speed to stop.
Paco: "Good."

Note that in this sample, both linguistic and nonlinguistic inputs are handled by the interface. Collagen's theory of discourse is based on the work of Grosz and Sidner (1986), which includes information about the current focus of attention in the task as well as the mutually believed plans of the dialog participants. Ongoing work uses Collagen to develop NLIs for GUI applications (Sidner, 2004).

There are many other examples of NLIs that make use of sophisticated dialog management that cannot be discussed at length in this article. One particularly notable interface is the TRIPS system (Allen *et al.*, 2001). This broad body of work includes an emphasis on issues involving speech acts and planning (*see* **Speech Acts and Artificial Intelligence Planning Theory**). We now turn our attention to the future of NLIs, a future being driven by technological advances in computer hardware, particularly in regard to alternative communication modalities used by people.

The Future of NLIs: Integration with Other Communication Modalities

We saw with the Collagen-based system, Paco, the ability to handle nonlinguistic inputs as part of the NLI. Another recent development with interfaces is the ability to combine the linguistic and nonlinguistic inputs into a single user communication. This type of input is known as multimodal input and has been shown to improve accuracy in human–computer communication (Oviatt, 2000).

An example of such a system is Smartkom (Wahlster *et al.*, 2001). Smartkom merges ideas about user interfaces from spoken interaction, GUIs, and natural gestural interaction (e.g., touch-screen technology) into a single system. As part of the project, a set of large-scale WOZ experiments were conducted that captured both audio and visual data in order to develop statistical language models based on machine learning techniques (*see* **Language Processing: Statistical Methods**). In addition, the system makes use of both NLG techniques and graphical displays for communication with users. Two other representative systems that use multimodal communication are the AdApt system (Gustafson *et al.*, 2000) and the MATCH system (Johnston *et al.*, 2002). These systems demonstrate how NLIs can evolve to be incorporated into more complex interfaces that exploit even more of the means by which humans have been able to communicate with each other – and are now able to use in a limited fashion with computers as well (*see* **Multimodal Interaction with Computers**). In general, the future of NLI research and development should see continued efforts in this type of integration work with other modalities. In addition, there should be continued application of more advanced core techniques in NLP, particularly in the area of dialog management, that will increase the range of communicative power by which computer applications can interact with human users.

Natural Language Processing: Overview

P Jackson and F Schilder, Thomson Legal and Regulatory, Eagan, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

We have seen the rise of Internet publishing for fun and profit coupled with increased velocity of both private and business communications by cellular phone and electronic mail. Information accessories, such as Web browsers, search engines, and personal digital assistants, have become commonplace. New modes of behavior have developed around such everyday activities as purchasing goods, accessing entertainment, and conducting business, enabled by mass connectivity and affordable bandwidth.

The medium of all these communications and transactions is still primarily natural language, albeit embedded in a framework that includes hypertext markup and is capable of being augmented by multimedia. Various forms of language processing provide access to Web sites, access to products and services within those sites, and organizational principles for navigating and browsing Web pages. The supporting technologies range from the simplest keyword search to more sophisticated methods that use statistical models of language.

The goal of applied research is to put customers at the center of the design process and to use technology to enable their wishes and to amplify their abilities. Successful applications are not usually built from solutions in search of a problem; rather they are carefully crafted combinations of science and engineering that focus upon providing a well-defined set of capabilities. Considerations such as cost, scale, and speed also are paramount in calculating how much performance can be delivered at a price that customers are prepared to pay.

Successful natural language applications typically involve deploying more than one such technology. Thus the ability to parse free text is of limited utility unless one can also extract, interpret, and collate semantically meaningful units of information from documents. Successful deployment also requires that these technologies be fielded in a manner that is carefully tailored to a problem-solving context. Thus, while general-purpose parsers are useful research vehicles, such programs tend to find commercial application only if they can be customized to a particular task or trained on data drawn from a problem domain. There are many kinds of documents – such as news, financial reports, scientific and medical articles, contracts, court reports, and public records – that have their own peculiar format, structure, and vocabulary. Programs to process these data will normally need to incorporate some prior knowledge of both the purpose of such documents and their significant features, such as proper names, dates, monetary amounts, and other identifiers that are highly context-specific.

For example, the Deal Proof software for proofreading legal contracts deploys a pattern-learning algorithm that first identifies recurring phrases in a document, or collection of documents. The language employed in contracts is highly variable, if one considers the whole gamut from simple rental agreements to complex mergers and acquisitions, and so it is not feasible to write a parser that will perform a complete analysis of unseen documents. First, significant patterns of language must be anticipated or discovered, as a prelude to checking consistency in the usage of terms and phrases, together with their definitions and qualifications. Only then can the program identify parts of the document that might be problematical, e.g., because instances of these patterns conflict. In any event, the user remains in the driver's seat, so the program is functioning as an intelligent assistant, rather than as a decision maker.

Getting the right allocation of function between person and machine is always extremely important in knowledge-based systems, and natural language applications are no exception. In this context, it is useful to distinguish between application components that are tools and those that are appliances. It was Norman (1999) who first promulgated this distinction in an information setting.

- A **tool** is an artifact that amplifies the skill of the user, but also requires skill for its use.
- An **appliance** is an artifact that performs some function, and requires minimal skill on the part of the user.

For example, most search engines function as tools, because a user's result is only as good as the query the user has crafted. By contrast, document categorization programs ought to function as appliances. They are either capable of classifying documents correctly to some level of accuracy, or not.

As we shall see, this distinction is not always so simple to make. When multiple technical approaches are combined, some of these tool and appliance properties can be interwoven. For example, Google is a search engine, and therefore a tool, but it has some appliance-like characteristics. As well as employing an extended form of natural language indexing, it also exploits the link structure of the Web to give preference to popular sites. As a result, it is often able to deliver good search results when faced with underspecified queries.

This article outlines new application areas for natural language processing enabled by the advent of the World Wide Web, and describes some of the advances that have been made to date (see Jackson and Moulinier, 2002, for a more extended treatment). The emphasis is upon showing how research results outlined elsewhere in this encyclopedia can be exploited to create products and services that have genuine value, either in a commercial arena or in some nonprofit setting, such as government, academia, or healthcare. We begin with a rather simple map of the natural language concept space, show how combinations of such concepts can create interesting capabilities, and outline areas where further challenges and opportunities exist.

Application Areas and Technologies

There are many applications of natural language processing (NLP), some of which appear to be quite disparate from each other. However, they can be systematically compared and contrasted by considering some underlying properties. Two dimensions are particularly useful.

1. The degree to which the application **reproduces** or reinstates some linguistic phenomenon versus a requirement to **transform** or translate it.

2. The degree to which an application **recognizes** or analyzes linguistic input versus a requirement to **generate** or synthesize linguistic output.

These properties are neither absolute nor mutually exclusive. Almost all applications involve recognizing linguistic units and reinstating linguistic information, e.g., by looking up a word in a lexicon. By the same token, most NLP programs generate linguistic output in some form, whether in the form of annotations or text itself. However, most programs have a primary function that can be seen as either analytic or synthetic, while most programs work either by reproducing some linguistic stimulus, e.g., finding the right document, or transforming it, e.g., translating a document into another language.

Figure 1 attempts a rough and ready categorization of NLP applications based upon these two dimensions, which we represent as being orthogonal.

Document categorization, as used herein, denotes an application that seeks to sort documents into categories based upon the language that the documents contain. This activity can be distinguished from other, related activities, such as classifying documents by author, publisher, or type of document (e.g., letter, report, poem, e-mail). Whether a document is placed in one, more than one, or no categories, the activity is basically the same from a functional point of view in that it involves no material changes to the document or its language. The difficulty of the task is typically a function of the number of categories the program has to choose from and the complexity of the underlying taxonomic structure.

Figure 1 Natural language applications.

If, instead of classifying documents to an existing category scheme, we somehow group documents into **clusters** by similarity of content, then we are engaged in a more generative activity, particularly if the program also suggests names for the clusters, based upon the language in the relevant documents. Hence, this activity is allowed to straddle the Recognition-Generation dimension. But it remains close to the Reproduction end of the spectrum, because even then the documents are not changed in any way.

By contrast, **machine translation** (MT) is inherently an exercise in transformation that involves both recognition and generation. Analysis of the input language generates correct word and phrase translations for weaving into a sentence in the output language. The Reproduction aspect of lexical access is dwarfed by the word disambiguation problem inherent in the transformation, which, absent a solution, will generate outputs that are humorous or incomprehensible.

Document retrieval is perhaps the most obvious activity under the heading of Reproduction, because its primary purpose is to locate and present text that appears to be relevant to some information need. Recognition provides the underlying means by which query terms and indexing terms are matched and weighed. The closer the correspondence, the higher the returned documents are ranked by relevance. We include document filtering under document retrieval, even though a filtering process may actually suppress documents. This kind of 'negative retrieval' is a key component of spam filters and software designed to protect minors from objectionable material on the Internet.

We can distinguish **question answering** from document retrieval in the following way. Question answering generates an intelligible answer to a specific question, rather than presenting a user with a list of documents to sift through in search of an answer. Furthermore, this answer may be synthesized from multiple documents, instead of being drawn from a single document.

Summarization is primarily a generative activity, but there are, roughly speaking, two different ways in which a summary can be produced. One is to select and combine snippets of text from the document to be summarized, and could involve something as simple as identifying the most representative paragraph and presenting that to the user. The problem is then selecting the right text to reproduce. The other is to somehow create a 'gist' summary, or paraphrase, that does not rely upon actual wording from the document but which nonetheless captures its salient contents. This approach involves transforming text from the document, as a student would summarize a document in his or her own words.

The extraction of **named entities** and other information from text also has two aspects. One involves simply identifying the extent of names in the text, so that they can be extracted in one piece, without losing any information or importing any extraneous material. The emphasis is therefore upon accurate selection and reproduction. Another aspect involves the attempt to reduce a proper name to a canonical form with which one can perform further processing, such as **entity resolution**, e.g., by consulting a database or on-line directory to identify the actual person or organization. This activity involves transforming found names according to some standard scheme, and requires some kind of semantic representation of the underlying entities.

Finally, both **speech recognition** and **speech synthesis** involve transforming an input from one modality to another. Thus speech recognition transforms a physical sound signal into a symbolic structure representing the spoken words, while speech synthesis transforms such a structure into spoken words. The obvious difference between them lies not so much in the direction of the transformation but in the locus of the difficulty associated with each of these tasks. Speech recognition involves transforming a highly ambiguous and noisy signal into an unambiguous representation, while speech synthesis involves transforming an unambiguous representation into a human-sounding speech signal.

In what follows, we shall discuss example applications drawn from all four quadrants in Figure 1, concentrating upon document retrieval, information extraction, document categorization, and summarization/question answering. These four areas were chosen as exemplars because they are highly representative of the kind of applications that are found upon the World Wide Web or in organizational intranets.

The Role of NLP in Modern Applications

Early attempts to apply NLP were focused upon three main areas: machine translation, speech recognition, and database access. Leaving machine translation to one side for a moment, NLP was largely seen as a medium for person–machine interaction, in which people would be able to talk to computers instead of typing, or extract information from databases without using a special syntax. Nearly fifty years later, the vast majority of computer users are still typing commands, clicking through menus, and issuing database queries in the good old-fashioned way. Meanwhile, machine translation looks almost as difficult as ever, thanks to the intractability of the natural language understanding problem. Although advances have been made in MT, none of these rest upon providing a solution to one of the central problems of artificial intelligence (AI), namely, how to endow machines with enough knowledge of the world to make sense of simple sentences and draw trivial inferences from them. This is an aspect of the 'commonsense reasoning' problem, an area of AI in which progress has arguably been slow. Nonetheless, MT software can certainly function as an aide to human translators in a person-machine system in which humans perform pre- and post-editing (*see* **Machine-Aided Translation: Methods**). Again, we see the importance of getting the right division of labor between person and machine.

Over the last two decades, the emphasis in NLP has shifted away from these three traditional research areas toward applications that in some way amplify human intelligence in the performance of some information-processing task. Applications such as Internet search, automatic summarization, and text classification/clustering can mostly be viewed as tools and appliances that help users find, select, comprehend, and group documents. Most of the NLP techniques involved in information retrieval (IR) applications involve little AI of the traditional kind, where the emphasis was upon knowledge representation, deductive inference, and modeling the plans and intentions of individual speakers and writers. Instead, the recent emphasis has been upon statistical methods for modeling the language of entire corpora (*see* **Corpus Linguistics**). Probabilistic machinery for profiling documents and matching them to queries or categories has largely replaced cognitive models based upon linguistics, psychology, and epistemology.

The new approach to NLP is largely rooted in the statistical analysis of language. It is sometimes characterized as 'empirical' NLP, because it distills data about linguistic patterns from large text corpora, such as news feeds and Web pages. Unlike symbolic NLP (*see* **Symbolic Computational Linguistics: Overview**), which tends to work top-down by imposing grammatical patterns and meaning associations upon texts, empirical NLP tends to work bottom-up from the texts themselves, finding regularities which may or may not correspond to purely syntactic or semantic relationships.

The symbolic approach is still around, of course, and is applicable to many practical situations where the right corpora do not exist. Furthermore, there are applications where absolute accuracy is so important that any solution requires both handcrafting of the program and hand-correction of the program's output. However, Armstrong (1994) identifies a number

of advantages to the corpus-based approach with regard to addressing some of the key problems of NLP.

- **The problem of acquisition.** It relieves at least some of the labor involved in the hand identification and coding of linguistic information.
- **The problem of coverage.** It helps account for all of the phenomena associated with a given domain, or set of documents.
- **The problem of robustness.** It has a greater potential to accommodate actual language usages that may not be accounted for in 'official' language models.
- **The problem of extensibility.** It provides some basis for applying existing models and data to new domains or document sets.

The growth of the World Wide Web has only confirmed the importance of scale in NLP applications, driving home the realization that computationally expensive techniques for analyzing text are infeasible when one is faced with billions of documents. Coverage is an important aspect of scale, given the diversity of documents available on the Web, and so is robustness, given the high degree of variation in their linguistic style and format. Although there exist on-line directories of information (such as Yahoo!) that have been constructed largely by hand, it is hard to believe that this is the way forward.

NLP for Information Retrieval

In the past, commercial information retrieval technologies employed minimal NLP, often no more than the simplest stemming algorithms. But the globalization of business, aided and abetted by the World Wide Web, has increased demand for linguistic tools that are capable of processing languages other than English (*see* **Web Searching**). Many non-English languages require a more sophisticated treatment of tokenization and morphology for the purposes of indexing and retrieval.

Earlier experiments suggested that stemming delivers only modest improvements to retrieval performance on English documents, but such is not the case for languages such as French, which are much more inflected and have many more classes of irregular verbs, or for languages such as German, where additionally nouns are both compounded and case-inflected (*see* **Stemming**). Tomlinson (2001) suggests that modern approaches to stemming deliver double-digit performance gains up to 50% for many European languages, including significant improvements of more than 10% on English documents. Finite-state approaches have proved to be successful vehicles for this kind of analysis, judging from the number of toolkits that now use cascaded finite automata to layer different levels of linguistic processing. In a typical scenario, tokenization is followed by part-of-speech tagging, morphological analysis, and other, more domain-specific, analyses, such as the identification of proper names.

Experiments have shown that named entity recognition (NER) is also a significant factor in document retrieval; this result is both intuitive and unsurprising (*see* **Named Entity Extraction**). Many proper names are orthographically identical to non-names, and any confusion between the two is bound to affect search-engine performance. Name clashes and name variants can pose similar problems, e.g., in those instances where persons have the same name, or where company names have acronyms and other short forms. NER has implications beyond document retrieval, of course, in that linguistic processing of names is essential to many other tasks in the four quadrants of Figure 1. Nevertheless, the NER task is a core issue in information retrieval as broadly construed, and will therefore be dealt with here.

Successfully identifying and tracking name occurrences requires an indexing scheme that is more sophisticated than the typical inverted file structure in which individual words are tagged with the documents in which they occur. One approach is to construct a controlled vocabulary of terms, some of which may be multiword expressions, and add these terms to searchable fields in documents that feature the corresponding entities. The challenge for NLP is to provide automated assistance to what would otherwise be an extremely arduous and expensive editorial effort.

Wasson (2000) describes an Entity Indexing program at Lexis-Nexis in which names are treated as controlled vocabulary terms that can be searched for in certain document fields using special query syntax. Such indexing must be automated, given the sheer volume of daily news feeds. As noted earlier, one complication is that proper names, such as the names of companies, typically have shortened forms that are ambiguous when viewed in isolation. Thus the name 'American Airlines' may be used in the first paragraph of an article, but the short form 'American' or the abbreviation 'AA' may occur subsequently. Reliable name identification requires the ability to generate and recognize such variants. Wasson reports precision and recall of more than 90% on the indexing task.

The quality of these results is consistent with reports from the Message Understanding Conferences, or MUCs, (*see* **Text Retrieval Conference and**

Message Understanding Conference), which provided a stimulus for research and development in information extraction during the 1990s. In the 7th such conference, there was a track devoted to named entity recognition, with data collections and test conditions being set up along the lines of earlier conferences. The best MUC-7 system came from Edinburgh University, and employed a variety of methods, combining lists, rules, and probabilistic techniques, applied in a particular order.

First, the program applies a number of heuristic rules to the text that rely heavily upon syntactic cues in the surrounding context. For example, in *John Smith, director*, we know that *John Smith* refers to a person, because a string of capitalized words followed by a title or profession indicates the name of a person with high reliability. Then all named entities already identified in the document are collected and partial orders of the composing words are created. For example, names and name parts such as *Lockheed Martin Production*, *Lockheed Martin*, *Lockheed Production*, *Martin Production*, *Lockheed*, and *Martin* will be gathered and marked as possible organizations. The system then looks for short forms of personal names, such as *White* when *James White* has already been recognized as a person, and to label company names, such as *Hughes* when *Hughes Communications* has already been identified as an organization.

An alternative approach to NER is to write a program that uses **Hidden Markov Models** (HMMs) to learn how to recognize names. Some key work in this area derives from BBN Technologies, and resulted in the Nymble system (Bikel *et al.,* 1997), which also participated in MUC-7, and has since morphed into the more highly developed Identifinder system.

One way to think about NER is to suppose that the text once had all the names within it marked for our convenience, but then the text was passed through a noisy channel, and this information was somehow deleted. Our task is therefore to construct a program that models the original process that marked the names. In practical terms, this means learning how to decide, for each word in the text, whether or not it is part of a name. Typically, we are also interested in what kind of name we have found, so the word classification task reduces to deciding which name class a word belongs to. For convenience, we include NOT-A-NAME as a name class.

As with the heuristic approach, it is necessary to identify features of words that provide clues as to what kinds of words they are. The Nymble system used the features shown in Figure 2, which sort all words and punctuation into one of fourteen categories. Although these word features are not informative enough in themselves to identify names, or parts of names, reliably on a word-by-word basis, they can be leveraged, in conjunction with information about word position and adjacency, to provide better estimates of name class.

Word Feature	Example Text	Explanation
twoDigitNum	90	Two-digit year
fourDigitNum	1990	Four-digit year
containsDigitAndAlpha	A8-67	Product code
containsDigitAndDash	09-96	Date
containsDigitAndSlash	11/9/98	Date
containsDigitAndComma	1,000	Amount
containsDigitAndPeriod	1.00	Amount
otherNum	12345	Any other number
allCaps	BBN	Organization
capPeriod	P.	Personal name initial
firstWord	The	Capitalized word that is first word in a sentence
initCap	Sally	Capitalized word in midsentence
lowercase	tree	Uncapitalized word
other	.net	Punctuation, or other word not covered above

Figure 2 Nymble's word feature set, based on Table 3.1 from Bikel *et al.,* 1994.

Their approach is based on the commonly used bigram language model, in which a word's probability of occurrence is based on the previous word. The needed probabilities are estimated from corpus counts, as usual. Sparse and missing data are handled by back-off models and smoothing.

Although named entity recognition is close to being a solved problem, few search engines offer specialized name searching. This is despite the fact that, if proper names were recognized as such, orthographically identical non-name terms would not bring back irrelevant documents. The main drawback to providing such a feature is the computational cost of query processing on the front end and document loading on the back end. A user can specify that part of a query is actually a name, as in the Lexis-Nexis example cited above, thereby saving query-processing cycles that would be required for name recognition.

Figure 3 Cascade of modules in an information extraction system.

But the additional space and CPU time required for name identification and name indexing at load time still looks like a substantial overhead cost to many on-line publishers.

With regard to other possible contributions of NLP to the practice of information retrieval, there is some truth in the observation that the current technology is "either too weak to have a measurable impact . . . or else too expensive to be cost-effective" (Tzoukermann *et al.*, 2003).

NLP for Information Extraction

The ability to identify named entities is useful for both information retrieval and document linking (*see* **Information Extraction, Automatic**). But this quickly leads to the desire to identify also the relationships in which such entities participate. There has been interest in obtaining automatically more and more information from both individual documents and whole corpora. At the document level, this activity is generally described as 'information extraction'; at the corpus level, it is more often referred to as 'text mining' (*see* **Text Mining**). One important subproblem is that of event extraction, in which we seek to identify the 'who', 'when', 'where', and 'how' of an event, and assign the correct roles to participating parties, times, places, and instruments. Another important subproblem is that of entity resolution, in which we seek to identify unambiguously the referents of proper names associated with events.

Event Extraction Intelligence agencies have been using computers to screen electronic news feeds and communications traffic since the 1970s. In the past, programs would look for key terms, such as *oil* or *bomb*, and analysts would sort through the documents found. But modern extraction programs go further in attempting to identify, extract, and present interesting events and relationships. An information industry has grown up around 'homeland security' in the United States, as demand for more sophisticated tools has increased. The majority of such toolkits feature an information extraction capability, as well as other tools, such as document clustering and data visualization.

Unlike more ambitious forms of NLP, information extraction programs usually analyze only a subset of any given text, e.g., those parts that contain certain 'trigger' words, and then attempt to fill out a fairly simple data structure that represents objects or events of interest. Thus, if our focus were corporate takeovers, we might be interested in who acquired whom, and for what price. Similarly, if we cared about personnel changes among senior executives or board members in large corporations, we might want to know who vacated what positions and who was hired to replace them.

Information extraction can be regarded as a subfield of NLP that focuses upon finding rather specific facts in relatively unstructured documents. No practitioner would claim that his or her program 'understands' the text, or is artificially intelligent in the traditional sense. For the most part, such a program is simply recognizing linguistic patterns and collating them.

A common approach to parsing free text for information extraction is to separate different levels of linguistic processing into modules that are then pipelined together, as in Figure 3. Each stage or level consists of one or more pattern recognition elements, called finite automata. Earlier stages of processing recognize more-local linguistic entities, such as words and sentence boundaries, perform part-of-speech (POS) tagging, and work in a more or less domain-independent fashion. Later stages recognize more domain-specific patterns, necessitating knowledge of objects and events that will differ between applications. Thus the patterns to be recognized will differ across domains, as will the templates that need to be filled. Similarly, the knowledge required to merge filled templates successfully will be domain-dependent.

As Grishman (2003) states, a minimal event extraction system needs domain-specific stages that identify proper names, noun groups, verb groups, and finally recognize the event itself. Names need to be categorized to the domain, e.g., as to whether they represent persons, companies, places, etc., while for noun and verb groupings it is essential to identify the *head*, i.e., the main noun or verb in the phrase. Finally, there must be an event template that knits this information together, with the constituents in the right roles.

For example, the FASTUS approach to parsing (Appelt *et al.*, 1993) follows the general sequence of operations shown in Figure 3 and Figure 4. In the *Regular Expression Matching* phase, finite-state machines target specific noun and verb groups, and

Figure 4 Cascade of modules for an event extraction system.

then match them up heuristically, i.e., using rules of thumb that are not guaranteed to produce the correct parse. Thus, in the sentence,

> The home of the mayor of the city of Bogota suffered a terrorist attack.

the program might conclude that the mayor of Bogota or the city of Bogota underwent the attack, rather than the mayor's home. The *Template Filling* phase takes the patterns found in the previous two steps and puts them into some canonical form, storing them in a data structure. Thus the different sentences,

> Terrorists bombed the mayor of Bogota's home.
> The mayor of Bogota's home was attacked by terrorists armed with bombs.
> The home of the mayor of Bogota suffered a terrorist bombing attack.

should, in theory, all result in the same information being extracted, and the same structure being generated, along the lines of Figure 5. However, different wordings may result in slightly different extractions, thereby hampering recognition that these all represent the same event.

It is important to realize that, for current extraction technology to work, the information sought must be explicitly stated in the text. It cannot be merely implied by the text. For example, a court opinion might end with the words *I find for the plaintiff*, but unless there is other text in the document stating exactly what this means for the disposition of the case, such an extraction might have limited value. The lack of inferential capability can pose significant problems when programs extract text from documents that expect the reader to be able to draw simple conclusions.

Entity Resolution The success of information extraction technology has led to an interest in text mining, i.e., the ability to both extract useful data from text and then perform data mining upon the results. The key idea is to discover something interesting about the relationship between text and the world, e.g., what persons or companies an article is discussing, what trend or train of events a news story belongs to, and so forth. Thus, determining the correct referent of a proper name is crucial, as is dealing with ambiguous names and name variants. Current text mining efforts focus on elucidating within-document and cross-document relationships, typically

Field	Filler
TYPE OF INCIDENT	ATTACK

building metadata repositories, such as directories of persons (Dozier and Haschart, 2000) and historical relationships between court decisions (Jackson *et al.*, 2003).

For example, Dozier and Haschart describe an application that creates hypertext links from about a million attorneys and judges featured in cases published on Westlaw to personal biographies of those persons in West Legal Directory. The system, called PeopleCite, creates such links by extracting templates from text and linking them to biographical information in a relational database (see Figure 6). Their matching technique is based on a naïve Bayesian inference network, and since its deployment in June, 2000, the implementation has automatically created of millions of reliable hypertext links in millions of documents. Their experiments show that this combination of information extraction and record linkage enables them to link attorney and judge names in case law to biographies with an accuracy rivaling that of a human expert.

The central problem addressed by the program is determining whether or not two names refer to the same person, given the rendition of the names and any contextual information. For example, is the current biography of attorney James Jackson of Palm Springs, California, really the biography of a James P. Jackson practicing law in Sacramento, California, in 1990? Probably. Experiments have shown that PeopleCite can perform this task at 99% precision and 92% recall, which is as good as a human expert.

Once an attorney has been matched against West Legal Directory, a number of other browsing options become possible. In addition to jumping from an attorney's name in a case to that person's biography, one can also bring up all the cases that a particular attorney has litigated, or all the Law Journal articles an attorney has written. This is obviously not possible unless a real connection has been established between

Figure 6 Overview of PeopleCite Tagging System.

a possible name string in the text and an actual person in the world.

Another aspect of text mining relates not to reference but to relationships that exist between concepts, some of which might be hypothetical but nonetheless interesting. For example, the voluminous nature of modern biomedical research has led to ancillary research on the information processing side, aimed at the uncovering of possible connections between genes and diseases, or uncovering similarities among drugs. Arguably, this work began with attempts to connect unrelated literatures (Swanson and Smalheiser, 1997), and has since progressed to the direct mining of textual or semi-structured data for scientific hypotheses (Srinivasan, 2004).

This extension of data mining to textual sources is an interesting concept that is generating more research than applications at the present time. There are already products and services on the market that claim to be able to perform text mining across the World Wide Web, but one must treat these claims with skepticism at the present time. Although it is certainly possible to handcraft solutions that will mine interesting information out of a particular document type and collate that information for presentation, we are still a long way from being able to mine arbitrary text collections in this manner.

NLP for Document Categorization

Document categorization is an application of significant interest to digital librarians, on-line publishers, and intelligent agencies, to name but a few potential customers of this technology. In the early 1990s, a number of tools for this task made the transition from research laboratories to the marketplace, but their success was quite limited. Regardless of the algorithms employed, accuracy was lackluster and deteriorated rapidly as a function of the number of alternative categories the program had to choose from.

Many academic studies have shown that machine learning and document retrieval algorithms can be adapted to the task of text categorization. However, these experiments have typically confined themselves to a relatively small number of alternative categories. For example, Dumais *et al.* (1998) compared five different learning algorithms on the task of routing about 12,000 news stories to 118 categories. Their results were encouraging, and led the authors to conclude that "very accurate text classifiers can be learned automatically from training examples." But it is well known that the difficulty of performing classification increases with the number of alternative categories and inter-category similarity. No single machine-learning algorithm has demonstrated its usefulness from the standpoint of fielding larger, industrial-strength applications, e.g., in electronic publishing. However, researchers have shown that superior classification can be achieved through a combination of multiple classifiers (e.g., Papka and Allan, 1998).

Document categorization is an interesting technology because it can be harnessed to drive a multitude of applications, such as automatic indexing, supplementation and linking, document recommendation, and the enhancement of search results. Companies such as Northern Light and Vivisimo have shown how the clustering of Web search results into categories, typically displayed as folders, can simplify the task of picking through result sets in search of relevant documents. So long as the number of documents and the number of categories are manageable,

this kind of processing can be done in real time without affecting the speed with which the search engine delivers results.

Strictly speaking, document categorization and document clustering are distinct operations. Categorization programs typically assign documents among a set of predefined classes after having been trained on a set of sample documents for each class. By contrast, clustering programs attempt to discover such classes by grouping similar documents together, often based on the same metrics employed by document retrieval systems. Automatic categorization errors tend to be characterized by uneven performance across categories, while automatic clustering errors tend to be characterized by a decline in cluster quality as smaller and weaker clusters are formed to account for all the data. Both suffer from the problems of scale outlined earlier, in that performance tends to decline as a function of the number of underlying classes.

A major problem facing on-line information services is how to deal with the problem of scale when indexing or updating large document collections with respect to a rich set of categories. By 'large' we mean document collections containing hundreds of thousands or millions of documents. By 'rich' category sets, we mean classification schemes containing tens of thousands of categories, with membership in one category rather than another being based on fairly fine distinctions.

For example, a significant task in on-line publishing involves keeping encyclopedia, review, or survey products up-to-date. Such compendia typically summarize, annotate, and discuss other documents as they are published. Thus, each new document needs to be routed to the editor responsible for the relevant topical areas, preferably with suggestions as to where that document should be cited. Ideally, a document categorization engine should help determine both which products are relevant and which chapters or sections of those products would be good places for these documents to appear. In such a scheme, the table of contents associated with an encyclopedia, say, can be viewed as a taxonomy to which one would like to classify incoming documents.

The good news is that the chapters of such compendia typically contain both text and extant citations which provide material for building a statistical model of the language contained both in the chapter itself and in the already-cited documents. The bad news is that a multivolume series might have thousands of chapters or sections, many of them dealing with similar topics. In addition to dealing with relatively small numbers of categories, most reported document categorization efforts involve making fairly broad distinctions, e.g., separating news reports into topics such as sport, trade, finance, and so forth.

It is readily apparent that there is no simple algorithm that will solve the large-scale text categorization problems associated with on-line publishing, given the number and richness of the categories involved. A hand-written, rule-based approach would be quite impractical for such a category space. However, artful combinations of more than one classifier appear to give good results.

For example, Al-Kofahi *et al.* (2001) used this technique effectively to route case-law summaries to various secondary law volumes in which they should be cited. Incoming documents were classified to zero or more categories that represented the 14 000 chapters of American Law Reports. These suggestions were then reviewed by editors to ensure quality and to achieve balance in terms of the number of citations accorded to each chapter. The precision and recall of the system compared favorably with the work of human contractors, who were later replaced by the new person–machine system. Error data is fed back to the system to enable incremental improvement through retraining.

The most effective linguistic feature for representing both documents and their destination chapters turned out to be content-word pairs occurring within a relatively small window of text. This feature outperformed both bigrams and noun phrases by a substantial margin. Other features that turned out to be useful were citations within the documents being routed, and any additional classifications to other taxonomies that had already been assigned. As with most document categorization systems, the linguistic processing used was extremely shallow. Most systems do not even employ stemming algorithms, and many do not bother to distinguish tokens that are part of names from non-name tokens. This use of naïve linguistic models in such applications is hardly surprising, given that most academic research on text categorization has concentrated upon the distributional properties of individual tokens, or the 'bag of words' approach. This may also explain why the topics of document categorization and clustering were omitted from a recent handbook on computational linguistics (Mitkov, 2003).

Another application of text categorization is document recommendation, as exhibited by the ResultsPlus feature on Westlaw. ResultsPlus is a feature that recommends additional relevant material to case law searches on Westlaw, enabling users to perform more comprehensive research. The system suggests articles from Law Reviews and encyclopedia products that are relevant to user queries. ResultsPlus

recommendations are based on both the query text and the retrieved cases.

Spam filtering is another successful application of document categorization, as evidenced by products such as SpamBayes. The so-called naïve Bayes approach to binary classification is both well understood and has been used effectively on categorization problems where the number of competing categories is not too large. Such an approach is based upon the assumption that the probability of a term vector being generated by a document of a given class can be decomposed into a simple combination of the distribution of the terms within that class. This probability distribution is derived from word counts, while zero probabilities are avoided by smoothing. Recent experiments suggest that statistical approaches to spam filtering are far superior to keyword-based approaches (Androutsopoulos *et al*., 2003).

NLP for Summarization and Question Answering

Text summarization can be defined as a process that takes a document as input and outputs a shorter, surrogate document that contains its most important content (*see* **Summarization of Text, Automatic**). 'Importance' can be determined with respect to a number of different criteria. The most common reflect user requirements, such as being relevant to a given topic, or helping the user perform a certain task.

For example, intelligence agencies need to monitor message traffic for certain topics, or to have long documents that feature associated keywords or phrases summarized, but only with respect to certain chosen topics, such as terrorism. Similarly, people working in bioinformatics research or health technologies need to keep up with the latest research, new product developments, or changes to regulations and guidelines relevant to their profession.

From this list of potential consumers for automatic summarization, one can see that the range of text and media types serving as input for such a tool might vary greatly. The range may include single documents (news articles, books, etc.) as well as collections of texts (news streams, archives of papers or books, etc.). In addition, the input data could be a database of non-textual data (such as medical records, or data gathered from an observation camera) and only the summary would be textual, providing a concise high-level description of the data set.

Because of the wide range of possible users interested in automatic summarization tasks and of different input formats, the actual summaries may also vary considerably. Most basically, one can distinguish between a summary as being an extract or an abstract, with rather different implications. An **extract** is a summary that is constructed mostly by choosing the most relevant pieces of text, perhaps with some minor edits. An **abstract** is a gloss that describes the contents of a document without necessarily featuring any of that content.

In terms of the graph in Figure 1, a system that produces an extract would be placed along the reproduction axis, whereas a system that is capable of producing an abstract would be placed along the transformation axis. In both cases, one can think of summarization as compressing or condensing a document. An extract performs compression by discarding less relevant material, whereas an abstract performs compression in more sophisticated ways, e.g., by suppressing detail and replacing specific facts with generalities. Obviously, one could mix these two modes of compression in a longer summary, although doing this effectively raises many design issues.

In addition to this basic distinction between extracts and abstracts, summaries can be categorized according to their overall purpose.

- An **informative** summary is a compressed version of the original covering the most important facts reported in the input text(s) (e.g., summary of a journal article).
- An **indicative** summary reports only that certain topics were covered in the input text without providing further details (e.g., keywords for scientific papers).
- An **evaluative** summary gives an opinion on the input text most often by comparing it to similar documents (e.g., a book review).

Another distinction that one finds in the literature is between **generic** and **query-relevant** (or topic-focused) summaries. Generic summaries give an overall sense of a document's content, while query-relevant summaries confine themselves to content that is relevant to a background query. As we shall see, the features and mechanisms needed for query-relevant summaries also find application in question-answering systems where an answer for a specific question is found by consulting on-line sources or ready-made response repositories.

A question-answering system first has to analyze the question, then find the correct answer in the available resources (Internet, text collection, etc.), and finally prepare the answer accordingly to the user's profile together with supporting information (e.g., a link to the source).

Summarization Technologies Most summarization systems work by picking sentences out of the full text,

employing a mixture of linguistic knowledge and more generic statistical methods. A typical example of such a hybrid approach is that of the Trainable Document Summarizer (Kupiec *et al.,* 1995), which uses the following set of discrete features for selecting sentences:

- **Sentence length feature**. Summaries rarely contain really short sentences, so we expect sentences to be longer than a threshold, such as five words.
- **Fixed phrase feature**. Certain phrases suggest summary material, e.g., 'in conclusion'.
- **Paragraph feature**. The first and last several paragraphs of a document are most likely to contain summary material.
- **Thematic word feature**. The most frequent words in a document can be regarded as thematic, and summary sentences are likely to contain one or more of them.
- **Uppercase word feature**. Proper names and acronyms (especially with parenthesized explanations) are often important for summaries.

Every sentence in a document can be scored according to its probability of being in the summary using Bayes's rule, if we assume independence among the features. The prior probability can be approximated by a constant factor, such as the reciprocal of the number of sentences in the document, and therefore ignored. The other probabilities can be estimated from counts over training data.

Other features used in automatic summarization focus on the discourse level and try to address the overall structure of a document. There are two aspects of discourse structure that help find summary sentences. The first one is called **cohesion** and is concerned with different relations that can hold between text units of various sizes and content (e.g., words, phrases, word senses, or referring expressions).

By building a graph consisting of these text units and where the connections between the text units represent certain relationships between these text units (e.g., word similarity or co-reference), parts of the graph can be identified that are well connected in contrast to other parts that are less well connected or are even islands in the graphs. Paragraphs or sentences that contain many well-connected (or 'bushy') nodes are assumed to be good candidates for summaries.

Such an approach that takes into account several different relations holding between the words of several texts to be summarized in one summary can be found in Mani and Bloedorn (1997). They generate cohesion text maps that have the words of the texts as nodes, and the arcs represent adjacency, co-reference, and lexical similarity among other things.

Another aspect of discourse structure is **coherence**. Determining the coherence of a text by deriving the relations between sentences (or clauses) may also improve the performance of text summarization systems. Based on text structure theories such as **Rhetorical Structure Theory** (RST) (Mann and Thompson, 1988), summarization systems have been proposed that make use of the overall discourse structure of a text (see Marcu, 2000). Such approaches seem to be quite compelling for the summarization task because they try to model the way an author organizes a text. A coherence-based approach may also help with generating a coherent summary text; most current applications cannot provide this feature because they are extraction-based systems. Omission of material and lack of coherence are the two main problems facing automatic summarization.

Researchers have typically used two methods in trying to quantify the performance of summarization programs. One is to compare the machine's output with a human-written summary, produced by an editor or a domain expert. This has been called 'intrinsic' evaluation, and it is the more widely used of the two. The other, 'extrinsic', approach is to evaluate the usefulness of a summary in helping someone perform an information-processing task. Both methods are known to be sensitive to basic parameters of the experimental context, such as summary length.

Experiments have shown that a given pair of **human-written** summaries may only exhibit about 40% to 50% overlap in terms of their content. As Mitra *et al.* (1997) point out:

> If humans are unable to agree on which paragraphs best represent an article, it is unreasonable to expect an automatic procedure to identify the best extract, whatever that might be.

Extrinsic evaluations typically treat a summarization system as a post-process to an information retrieval engine. The summary generated is meant to be tailored to the user's query, rather than reflecting the document as a whole. Human subjects then use the summaries to decide whether or not the document is relevant to the query. Their performance on this task is measured with respect to time taken, the accuracy of their decisions, and sometimes the degree of confidence they are prepared to place in their decisions. The assumption is that, given good summaries, users will be faster to judge the relevance of search results than if they had to delve into the documents themselves, and that accuracy and confidence will not suffer too much.

These results illustrate both the imperfect state of automatic summarization and the imperfect state

of our evaluation methods. The evaluation of summarization technology may ultimately remain a subjective matter, because there is no unique right answer to the question 'What is a good summary?' for a given document or set of documents. Consequently, current studies tend to focus on evaluations based upon more than one model summary (Lin, 2004).

Further applications of summarization techniques go beyond summarizing a single text. These more recent trends take into account the information overload of a user or professional and try to facilitate processing the information a user has to cope with. Multidocument summarization systems represent the next logical step from Google News where news messages are only clustered according to a recent news theme. For example, the Newsblaster system (Evans *et al.,* 2004) is a multidocument system that creates one genuine summary composed out of several different news messages on the same topic. E-mail summarization tools must also deal with multiple texts as they summarize the gist of an e-mail thread.

So far, the output of summarization systems discussed produce text, but other formats are also possible. So-called multimedia summarization offers a totally new avenue of research and will lead to many new applications. The capability of taking multiple, different input formats (images, speech, video, music, etc.) and producing different mixed output formats makes this a powerful future application area. For example, the Broadcast News Navigator (Maybury and Merlino, 1997) is a tool for searching, browsing, and summarizing TV broadcast news from different news sources. The technology used for this application goes beyond pure text-processing techniques (e.g., video segmentation, face recognition, speech recognition), but language (as speech or text) combines all the different modalities information is presented in.

Another challenge for natural language processing is the summarization of text in different languages and the production of output in a language that the user understands. This new trend will combine machine translation technology with summarization techniques and allow Internet users around the world to have access to the content of the increasingly growing number of non-English web pages (see, e.g., Evans *et al.,* 2004).

In multilingual text summarization, one general and important requirement for a successful application is the capability to adjust to the user's needs. The findings of evaluation experiments have shown that a good general-purpose summary is difficult to determine. Moreover, user-oriented summaries generated by automatic summarization systems seem to achieve better scores than general-purpose summaries (Mani and Bloedorn, 1998). One consequence of this observation is that an ideal summarization system needs to understand the task at hand, and should be capable of inferring what question the user has in mind when looking for a document.

As pointed out earlier, there is a growing need to merge the two distinct areas of summarization and question answering. In the future, this development will most likely lead to more user-oriented systems that process natural language by engaging the user in a dialog on the user's task and her particular information needs. How current systems address the task of question answering will be discussed in the following section.

Question Answering Question answering (QA) can be contrasted with both information retrieval and information extraction (*see* **Question Answering from Text, Automatic**). In information retrieval, a query to a search engine typically returns a list of documents, ranked by relevance to the query. The specific information that the user needs is contained somewhere in one of these documents, if he or she is lucky. The answer to the user's research question is not usually ready to hand, unless the search was actually for the document itself, or for a URL. Information extraction, on the other hand, locates specific information, but the nature of this information is predetermined, and cannot be served up in response to an open-domain query.

The potential applications of question-answering technology are almost too numerous to list. Most users of search engines are not searching for particular documents, but for specific products, services, prices, people, and companies, not to mention a plethora of facts and figures.

The prototypical QA system is a pipeline model that processes the answers step by step in specialized modules:

- **Question Analysis**. Because the user asks a natural language question rather than a Boolean one where the syntax is precisely defined, some sort of linguistic analysis of the input query has to be carried out.
- **Document Collection Processing and Candidate Document Extraction**. The document collection can be preprocessed and text chunks may be tagged according to likely answer types (e.g., PERSON, DATE). The system has to retrieve a set of candidate documents that presumably contains the correct answer to the question asked.
- **Candidate Document Analysis and Answer Extraction**. Documents that are assumed to contain the

right answer are scrutinized more deeply, and a string, phrase, or paragraph is extracted that represents the correct answer.

- **Response Generation.** The answer format generated can range from a string limited by a fixed number of characters to a clarification question asked by the system to improve the search result.

Many different methods have been proposed and described in recent years, mainly presented at the QA track of the Text Retrieval Conference (TREC). For a concise overview of current QA systems, consult Harabagiu and Moldovan (2003), who offer a taxonomy of such systems, based upon a combination of language and knowledge resources, NLP techniques, and reasoning methods required. The systems discussed run the gamut from relatively simple processors of factual questions, through systems that must use some form of inference to deliver answers to more complex questions, to systems that are capable of debating or opining on more speculative issues such as future trends.

True question-answering systems allow the user to pose actual questions, rather than merely typing queries consisting of keywords. However, the reality is that such questions are subject to query processing that identifies keywords for searching. Such processing may be superior to that used in normal Boolean or ranked retrieval systems, e.g., it may involve the identification of proper names, but the query that is typically run is a Boolean expression based on the original question, possibly augmented by expansion terms from a thesaurus.

To overcome this shortcoming, recent systems try to make use of shallow semantic parsing techniques. Analyzing the question and the data collection, predicate-argument structures or semantic frames can be extracted. Based on the derived semantic representation, a better match of the question type and the potential answer candidate can be achieved. In addition, some sort of simple reasoning can be carried out with simplified logical forms derived for the questions and potential answers as well as for domain-dependent axioms (see Moldovan *et al.,* 2002).

The remaining piece of the question-answering puzzle is an answer-type taxonomy that represents the different kinds of questions that a user can pose, such as 'who', 'when', 'where', 'how much,' etc. Many taxonomies developed for QA, or used in QA systems, are built around WordNet (Fellbaum, 1998) (*see* **WordNet(s)**), by identifying semantic categories of nouns and verbs that represent key concepts in the domain, and then factoring in named entities that instantiate those concepts. Adjectives and adverbs are also needed to answer questions about properties of objects, which represent values of attributes or dimensions.

Future Directions

Statistical approaches to natural language processing have made significant contributions to the state of the art in application areas such as document retrieval, information extraction, and text categorization. Finite-state technology, originally developed for speech recognition, has since been successfully applied to other linguistic processing tasks. Named entity identification has progressed to the point that automatic enhancement of news and business information is now possible, by providing links from documents to the persons and companies that they reference. Text categorization algorithms can now route millions of documents to hundreds of thousands of categories with reasonable accuracy, and are also effective against spam e-mails.

Challenges for the future include the extraction of events and other fact patterns by means other than the laborious writing of rules. Summarization and question answering remain topics for further research, and are still in their infancy, as far as being able to deal with a broad range of document types. So-called 'concept search' engines, such as Recommind and DolphinSearch, are also quite rudimentary, relying as they do upon patterns of word co-occurrence, rather than upon concept identification.

It seems likely that applications of natural language processing will continue to drive research, as on-line information services, intelligence agencies, and healthcare professionals come to demand, and depend upon having, unlimited access to textual information. The tools and appliances needed to perform the tasks identified in **Figure 1** will need to be robust in coping with the real world problems of colossal scale and imperfect data. The NLP community has shown itself to be responsive to these challenges, and we can look forward to further advances.

Evaluation: Introduction and Terminology

Evaluation is the systematic application of methods, metrics, and measures for the assessment of computer applications for natural language processing. Community-based, task-focused evaluation has accelerated scientific advancement in areas such as automated speech processing, information extraction, and machine translation. Several other articles in this encyclopedia describe specific evaluation efforts in areas such as information extraction, question answering, and summarization. However, evaluation methods have much in common. This article motivates purposes for evaluation, introduces key concepts, terms, and metrics, and summarizes evaluation in several areas.

Evaluation involves methods, metrics, and measurements:

- The **method** is the general strategy or approach to evaluation, such as what is being evaluated (e.g., evaluation of a complete system or of individual components), who or what performs the assessment (e.g., a human such as an engineer or system user, a committee, or a machine), and how evaluation is performed, such as comparison with a standard data set, by other comparative means (e.g., human vs. machine, machine vs. machine), or by performance in support of a real task.
- **Metrics** are the specific relevant characteristics or properties to be assessed in the system, such as speed, accuracy, and usability. These can be quantitative and qualitative.
- **Measures** are the specific technical measurements assessed. For example, to assess the performance accuracy of information extraction systems and algorithms, typical measures include precision (the proportion of identified items that are correct) and recall (the proportion of items correctly identified).

Table 1 lists a few of the more popular measures used in natural language processing evaluations.

Evaluations should be informative, reproducible, comparable, and cost effective. By standardizing metrics and measurements applied to evaluate performance, the tests can be repeated and the multiple results compared. Evaluations should not be sensitive to data samples or evaluator error.

Motivated by research in information retrieval, evaluations typically depend on **test collections,** which include

- **documents** – typically a few thousand to a few million, which can be text, web, audio, or video documents;
- **queries** – typically between 50 and 400 characterizations of typical user information needs;
- **answers** – typically a set of document relevance judgments or extracted answers that have been

Table 1 Common evaluation measures for natural language processing

Measure	*Definition*
Word error rate (WER)	Minimum number of edits (insertions, deletions, or substitutions) required to created the reference from the hypothesis as a portion of the reference size.
Precision (P)	Portion of hypotheses that are consistent with the reference.
Recall (R)	Portion of references that are present in the hypotheses.
F-measure	Harmonic mean of P and R. $2PR/(P+R)$
Mean average precision (MAP)	Mean of average precision for a set of queries at a range of recall levels.
Mean reciprocal rank (MRR)	The reciprocal of the rank at which the first correct response is returned or 0 if none of the first n responses contain a correct answer. For a sequence of queries, MRR is the mean of the individual query's reciprocal ranks.
Detection error Tradeoff (DET)	Curves which show the tradeoffs between miss and false alarm rates at multiple operating points.
Equal error rate (EER)	The point at which the number of misses equals the number of false alarms. The intersection of the DET curve with the y–x line.

Equal error rate (EER)	The point at which the number of misses equals the number of false alarms. The intersection of the DET curve with the y–x line.

checked by humans or some combination of machines and humans.

This approach is in marked contrast to, for example, the field of human–computer interaction, which, in addition to task-based, formal experimentation (termed 'summative' evaluation), includes in its evaluation arsenal

- **cognitive walkthroughs** – evaluation done by experts who step through each task asking detailed questions;
- **heuristic evaluation** – evaluation by experts using well-defined heuristics or guidelines;
- **formative evaluation** – observational user studies, questionnaires, and interviews.

For example, in dialogue evaluation, researchers could use the TRINDI 'tick list' (TRINDI, 2001), aimed at triggering significant dialogue features such as error recovery. Also, simulation-based evaluation and Wizard-of-Oz experiments could yield novel insights. However, these are rarely used in the evaluation of natural language processing systems.

Researchers, product developers, program managers, and end users have distinct requirements for evaluation:

- **Researchers** need feedback on the performance of technical approaches on various realistic data sets to identify errors and limitations, to drive further algorithmic refinements, and to inspire new technical directions.
- **Product developers** need metrics (e.g., quality, performance, usability) that relate to user tasks so they can guide further development efforts.
- **Program managers** need to understand performance of capabilities to assess costs and benefits (e.g., cost savings, efficiency, productivity). They need to measure progress in order to manage cost and schedule and decide into which user communities to deploy solutions as well as where to invest in new technologies.
- **End users** need guidance on how well tools will work in their environments in order to make decisions on when, where, and how to use various tools.

Speech

The development of large training and test collections, often in concert with the Linguistic Data Consortium, and quantitative measures of performance on common tasks has been essential to continuous progress in speech processing. The standard word error rate (WER) metric is the minimum number of edits (insertions, deletions, or substitutions) required to create the reference from the hypothesis as a portion of the reference size. Figure 1 illustrates the reduction in WERs benchmarked by the National Institute for Standards and Technology (NIST) (Pallett *et al.*, 2000) since 1988 for a range of tasks including speech read from North American news sources such as the *Wall Street Journal*. More challenging tasks have included spontaneous speech, varied microphones, noisy environments, conversational speech, and foreign broadcast processing. Speech in meetings recorded with multiple distant microphones turns out to be one of the greatest challenges, giving very high error rates relative to broadcast news and conversational telephone speech.

Figure 1 History of speech recognition word error rate for best systems.

Following a 1995 pilot, a few years of broadcast news speech transcription evaluations led up to a 13.5% WER, half the error rate of the original pilot. This led to new research in spoken document retrieval and to a new program in topic detection and tracking (TDT). It also led to the Text Retrieval and Evaluation Conference (TREC) video retrieval track and the Automated Content Extraction program. Another important benefit of corpus-driven, community evaluation that is seen here is the ability to disseminate knowledge among research groups as they publish not only their performance results but also papers about methods used and lessons learned. The 1998 broadcast news tests included an evaluation of the extraction of named entities (i.e., people, places, organizations) from speech, exploring the relationship between WER metrics for speech transcription and precision and recall (and their weighted combination into an F-measure as defined in Table 1) for detection of named entities. For example, a team from Bolt, Beranek, and Newman Technologies (BBN) reported an 82% F-measure on a 14.7% WER. In the spoken document retrieval task,

measures included WERs for transcription together with mean average precision (MAP) for document retrieval. In 1998, the highest MAP of the spoken document retrieval systems was 0.567 by the University of Massachusetts. When teamed with Dragon Systems and AT&T the university achieved similar results (0.507 and 0.512) using their own recognizers.

Information Retrieval

A key venue for evaluating human language technology has been the Text Retrieval and Evaluation Conference (TREC). TREC is broken up into various task- and data-focused evaluation 'tracks.' TREC's annual cycle typically starts with data distributed in the spring, experiments run over the summer, and results presented at a fall conference.

One part of the evaluation process is the informal piloting of evaluations with a small group to establish evaluation data, methods, metrics, and measures, followed by broader participation. Figure 2 shows the level of participation by size of group in various TREC tasks from 1992 to 2003, growing from 22 to 93 participants. The graph illustrates the increase in diversity of evaluations over time. These included multilingual retrieval such as Spanish and Chinese (Mandarin Chinese), multimedia retrieval as in video story retrieval, finding novel information, and special domain focus such as genomic linkage and annotation to support retrieval. Also evident is the growth in participation in tasks such as *ad hoc* retrieval, web retrieval, very large test collection, and question answering. TREC is detailed further in a separate article (*see* **Text Retrieval Conference and Message Understanding Conference**).

Figure 2 History of participation in TREC tracks.

The Cross-Language Evaluation Forum addresses digital library applications by (1) developing an infrastructure for the testing, tuning, and evaluation of information retrieval systems operating on European languages (extending also to Russian, Japanese and Chinese [Mandarin Chinese]) in both monolingual and cross-language contexts, and (2) creating test suites of reusable data which can be employed by system developers for benchmarking purposes. A series of evaluation tracks, as in TREC, include mono-, bi- and multilingual information retrieval on news collections, mono- and cross-language information retrieval on structured scientific data, interactive cross-language information retrieval, multiple language question answering, cross-language retrieval in image collections and cross-language spoken document retrieval.

Text Parsing

Parsing text is one of the most basic of language technology tasks, including labeling parts of speech, semantic classes (e.g., person, object), and function classes (e.g., subject, direct/indirect object) of words and sentence constituents. The Parseval system (Black *et al.*, 1991; Harrison *et al.*, 1991) was initially applied to seven parsers (Black *et al.*, 1993) to syntactically evaluate broad-coverage English-language parsers using common test data. Semeval (Moore, 1994) is a Parseval-modeled plan to extend parsing evaluation to semantic analysis. An annual Semeval competition includes such tasks as word sense disambiguation and logical form. A related task is the creation of a treebank or set of sentences parsed correctly by hand by competent humans (Black, 1993) that serve as an answer key both for building and for evaluating parsers. *See* **Treebanks and Tagsets** for details on the separate use of treebanks as training data.

Question Answering

Question answering (QA) is the task of responding to natural language questions by providing answers extracted from free text (*see* **Question Answering from Text, Automatic**). The QA track in TREC uses the mean reciprocal rank (MRR) metric (defined in Table 1), which credits finding answers to questions as high as possible in the ranked output (i.e., the score on a given question is the reciprocal of the rank at which the first correct response is returned or 0 if none is returned in the first n answers). The best current systems answer simple 'factoid' questions (i.e., who, what, when, where?) about 70% of the time. More complex evaluation tasks being

investigated in 2003 included questions whose answer is a list or a biography and 'how' and 'why' questions. Tasks under consideration for evaluation include definitions of people and things, fixed domain QA, dialogue, answer justifications, relationship QA, opinion QA, multimedia and multilingual QA, and QA where there is no answer.

Fukumoto *et al.* (2003) described the Question Answering Challenge, a 16-system Japanese question-answering evaluation that involved both single and multi-answer factoid questions from two years of the *Mainichi Newspaper*. The systems could retrieve the answers, in the form of named entities (*see* **Text Retrieval Conference and Message Understanding Conference**), from newspaper articles or other information sources such as an encyclopedia, thesaurus, corpus of data, and so on. There were three tasks: providing the best five answers (Task 1), providing the best single answer (Task 2), and then answering a question followed by a series of follow-up questions (which contained anaphora and ellipsis) (Task 3). Two hundred questions were prepared for Task 1, 40 for Task 3. The most accurate of 14 systems evaluated in Task 1 achieved a MRR of 0.61. The best system returned correct answers in the first rank for more than 50% of the questions and in the top five ranks for more than 75% of the questions. The most accurate of 14 systems evaluated in Task 2 achieved a mean F-measure of 0.36. Only six systems were evaluated on Task 3 and 14 of the 40 questions could not be answered by any system. The best system achieved a 0.14 mean F-measure.

Multilingual Topic Detection and Tracking

Topic detection and tracking (TDT) research sponsored by the Translingual Information Detection, Extraction, and Summarization program (TIDES) of the Defense Advanced Research Projects Agency (DARPA) has held evaluations since a pilot in 1997. TDT algorithms discover and thread together topically related material in streams of data such as news wire and broadcast news in both English and Chinese (Mandarin Chinese) (Wayne, 2000). TDT evaluation includes the following five tasks:

1. **Story segmentation** – detect changes between topically cohesive sections
2. **Topic tracking** – keep track of stories similar to a set of example stories
3. **Topic detection** – build clusters of stories that discuss the same topic
4. **First story detection** – detect if a story is the first story of a new, previously unknown topic
5. **Link detection** – detect whether or not two stories are topically linked.

The primary metric of evaluation is detection error tradeoff (DET) curves, which show the tradeoffs between miss and false alarm rates at multiple points. A single number metric often used is the equal error rate, the point on the DET curve at which the number of misses equals the number of false alarms.

Information Extraction

The Message Understanding Conference and the Multilingual Entity Task explore the extraction from text of the names of entities (e.g., people, places, organizations), coreferences, properties, relations, and events in several domains (e.g., joint ventures, microelectronics) and many languages (e.g., English, Chinese [Mandarin Chinese], Japanese, Spanish). Performance measures include precision, recall, and F-measure (with recall and precision weighted equally). Today, entities can be extracted with more than 90% accuracy, relations with about 75% accuracy, and events with about 50% accuracy.

Summarization

The first large-scale evaluation of automatic text summarizers took place in May 1998 at the TIPSTER Text Summarization Evaluation Conference (SUMMAC) (Mani *et al.*, 1999, 2002). Summarization evaluation is challenging as answers cannot be simply classified as right or wrong, there is low human agreement on the best summary content, and notions such as fidelity to source are vague. Unlike intrinsic evaluations which judge the quality of the summarization, such as its fluency, coverage, or similarity to an ideal summary, SUMMAC investigated two extrinsic evaluations. In the first a summary was used to make document relevancy assessments and in the second it was used to categorize the document. SUMMAC established that automatic text summarization is effective in relevance assessment tasks. Summaries as short as 17% of full text length sped up decision making by almost a factor of two with no statistically significant degradation in F-measure accuracy.

Summaries can be simply extracts of phrases or sentences from the original source or newly generated abstracts of the source content. A Japanese version of SUMMAC using intrinsic evaluations found that human abstracts were better than human extracts, which were better than machine-generated extracts in terms of coherence and informativeness. These experiments also repeated English results that summaries (up to one-third of the source) save time (up to one-third) without loss of accuracy.

A complementary evaluation approach is readability/comprehensibility. In this approach to evaluation,

a user first reads a full source or summary and then answers multiple-choice questions about the text; the correctness of the answers indicates the quality of the summary (Hirschman *et al*., 1999).

Sponsored by TIDES and run by NIST, since 2000 the Document Understanding Conference has focused on the evaluation of summarization (Over and Yen, 2004). Evaluations have included assessments of both single and multiple document summarization at a variety of lengths (e.g., 10, 50, 100, 200, and 400 words). Evaluations have included both English and Arabic news clusters from TDT and TREC collections. The evaluation method compares system performance with both a human-authored ideal or 'model' summary and a system-created 'peer' summary. Metrics include content coverage (recall and relevance) and linguistic adequacy (e.g., human judgments about summary coherence, conciseness, repetition, clarity of referents, grammaticality, and formatting). Eighteen organizations participated in the 2003 evaluation.

Machine Translation

The first machine translation evaluations by the Automatic Language Processing Advisory Committee (ALPAC, 1966) compared the quality of unedited output with human translations (*see* **Machine Translation: History**). More recently, the TIDES-funded Machine Translation Evaluation Workshops, administered by NIST, use human judgments of fluency and adequacy (the degree to which the translated target corresponds to the meaning in a high-quality reference translation). This evaluation focuses on languages such as Chinese (Mandarin Chinese) and Arabic. Performance is assessed by automatic evaluation of machine translation using *n*-gram co-occurrence statistics based on IBM's BLEU system (Papineni *et al*., 2002). BLEU measures the *n*-gram precision of hypotheses with respect to references, with a brevity penalty for hypotheses that are too short. *n*-gram evaluation has a high correlation with human judgments and enables inexpensive and rapid feedback.

Dialogue Systems

Assessing the efficiency and effectiveness of human–machine dialogue is another important evaluation task. Objective measures include dialogue duration, the number and duration of user and system turns, the frequency of correction and repair turns, word error rate, the precision and recall of question answering in the dialogue, and transaction or task success. Subjective measures include ease of use, naturalness, clarity, and perceived robustness, speed, and quality. PARADISE (Walker *et al*., 1997) compares dialogue strategies on the same task using a weighted linear combination of measures. The assumption is that optimal dialogues will maximize user satisfaction by minimizing costs (time, recognition errors) and maximize task success. DARPA's creation of the Galaxy Communicator plug-and-play spoken language architecture enables developers to combine various components and evaluate them gracefully across modalities, from speech-only to interfaces that include graphics, maps, pointing, and gesture (Bayer *et al*., 2001). Walker *et al*. (2002) reported a DARPA Communicator cross-site evaluation in June 2000 of nine spoken dialogue travel-planning systems (AT&T, BBN, CMU, Colorado, IBM, Lucent, MIT, MITRE, SRI), resulting in a corpus of 662 dialogues. Evaluations varied different back ends, different modules (automated speech recognition, text to speech, and language understanding), and different dialogue strategies for managing mixed-initiative interaction.

Conclusion

This article has reviewed methods in evaluation in a range of natural language processing research areas including speech transcription, text retrieval, information extraction, multilingual topic detection and tracking, parsing, question answering, summarization, machine translation, and dialogue. Common among research in this evaluation is an emphasis on shared data, common tasks, and research community evaluation conferences. Future evaluations need to include focus on user-centered evaluation, systems issues such as portability, multilinguality and multimodality, and rapid and inexpensive evaluations. Finally, evaluation should not stifle innovation, creativity, and risk taking but rather balance assessment of continuous progress with fostering of revolutionary ideas.

'Understanding' Natural Language

Can computers be made to understand natural language? At first sight, the question does not even seem to make sense. Surely understanding is a mental state, and it is difficult to see how you can attribute mental states to devices made out of wire and silicon, no matter how complicated they are.

Yet computational linguists persistently talk about '**natural language understanding systems**' and about '**meaning representations**.' In order to see more clearly what is meant by these terms, we need to consider the circumstances in which it would be reasonable to say that a computer system 'understood' what it heard or read.

When would you be sure that another person had understood what you said to them? You cannot get inside their heads to inspect their mental state. The only way you can assess whether they have understood you or not is by inspecting their behavior. If their actions are related to what you wanted them to do, there is a fair chance that they understood you. If they are not, then either they did not understand you, or they do not wish to cooperate with you. It can be difficult to distinguish between these two, but if their behavior does reliably correlate with what you believe your utterances mean then you would tend to conclude that they did understand you (I use the term 'utterance' to mean a piece of spoken *or written* language produced in a context for some purpose, since both forms raise very similar questions when we are thinking about how to make a computer understand something. I similarly use the terms 'speaker' and 'hearer' to talk about the individual who produces or apprehends an utterance, regardless of whether it is spoken or written).

This is, of course, a way of testing whether someone has understood something rather than a definition of what understanding is. As such, it is a test that could be applied to a computer system. If a computer system reliably responded to utterances by taking actions that seem appropriate, then it would be difficult to say it did *not* understand you.

Passing this test would not guarantee that the computer was in the same kind of mental state as a person whose actions were equally appropriate. It is very difficult to see what kind of test *could* be used to investigate this. If a system did not respond appropriately then it would be reasonable to conclude that it was *not* in a mental state similar to the state of a person who understood what was being said, but no observation could show that it *was* in such a state. The best we can do, then, is try to make systems that display appropriate behavior. This test is a subset of the **Turing test**, which suggests that if you could not tell whether you were conversing with a computer or a person then it would be difficult to say that the computer was *not* intelligent. It may be that there is something ineffable about the mental state associated with understanding. Whether there is or not, developing computational models that behave as though they understood what they were told is difficult enough.

Conversational Agents

What kind of behavior would a system that understood natural language display? When people use language to communicate, they display two distinct sorts of behavior: they produce utterances that respond to what they have just heard, and they carry out actions that are linked to what they have just heard.

How could we produce a computer system that carried out either of these kinds of behavior? Weizenbaum (1966) noticed that in certain circumstances you can produce appropriate utterances simply by making systematic changes to what you hear. If someone is pouring out their troubles to you, you can sound sympathetic if you take what they say and turn it around:

(1) PATIENT: My mother always hated me.
DOCTOR: What makes you think your mother always hated you?
PATIENT: I was shouted at nearly every day.
DOCTOR: Did it upset you that you were shouted at every day?

Transformations of this kind can be carried out by very simple pattern-matching algorithms. When you are trying to help somebody to work through their problems by letting them talk about themselves without casting judgment on what they say, you can make a number of simplifying assumptions:

- Almost everything that is said will be about the speaker and his or her relationships with other people.
- Almost everything that is said will be about some sort of problem, and most of it will be a judgment rather than a statement of fact.
- The speaker is not expecting you to add anything substantive to what he or she has said. In fact, your role requires you *not* to say anything substantive.

```
[my ?X me]  ==>  [what makes you think ?X you]
[I was ?X]  ==>  [did it upset you that you were ?X]
```

Figure 1 Sample ELIZA-like rules.

In these circumstances, rules, each of which has a left-hand side that matches the user's input and a right-hand side that inserts matched elements of the input into a canned phrase, can be used to generate reasonable sounding responses. A set of patterns such as the ones in Figure 1 will produce reasonable responses to most of what the 'patient' says. A set of rules such as these will produce individually satisfactory responses. It is important to be careful to turn every single occurrence of '*me*' and '*I*' to '*you*,' and every single occurrence of '*my*' to '*your*,' and to change '*am*' to '*are*,' and so on, to avoid exchanges like (2):

(2) PATIENT: I was always arguing with my parents.
DOCTOR: Did it upset you that you were always arguing with my parents?

So long as we take a bit of care about things like this, the responses to each sentence in isolation will be fairly sensible. To maintain the illusion of a sympathetic listener over a sustained dialogue, however, it is important to keep track of the rules that have been fired at earlier stages. The following is taken from a dialogue with a freely available implementation of Eliza (distributed as part of the Emacs text editor):

(3) PATIENT: My mother always hated me.
DOCTOR: Tell me something about your family.
PATIENT: My father was very cruel,
DOCTOR: You seem to dwell on your family.
PATIENT: My family was the cause of all my problems,
DOCTOR: Are you hung up on your family?
PATIENT: Yes
DOCTOR: I see . . . . Well, why do you say this is so?
PATIENT: Because they treated me badly.
DOCTOR: Is it because they treated you badly that you came to me?
PATIENT: Yes.
DOCTOR: Yes, hmmm . . . so, what makes you believe this is so?

Looking at this dialogue, it is clear that this implementation contains the rules in Figure 2.

Once a rule has been applied, it is shifted to the end of the rule set so that it does not get used again too soon, since otherwise the dialogue will become very repetitive. Even so, conversations tend to die out after a while, particularly once the 'doctor' has asked a polar question (e.g., *Are you hung up on your family?*). If the patient just says '*yes*,' the doctor has very little to go on for its next move, and hence it will only be able to respond with very generic utterances. If the patient's utterance does not contain any key words, then it will not match any rules with content words in their patterns, and hence the response will either be completely generic (*I see . . . . Then what makes you think this is so?*) or it will just be a variation of what the patient said (*PATIENT: Are you just a box of tricks? DOCTOR: What makes you believe are me just a box of tricks?*). (Note that, in this example, the rule that was triggered failed, as discussed previously, to convert '*are you*' to '*am I*,' let alone to '*I am*' as would be required for the response to be well-formed.)

This kind of approach to making a '**conversation agent**' (or '**chatterbot**') has a number of evident limitations, but it does show what can be done by exploiting the user's expectations. In certain situations these expectations can be extremely low in terms of 'added value' by the system – ELIZA mimics the surface behavior of a Rogerian nondirective psychotherapist, where anything other than rephrasing of the user's input is actively discouraged, and another well-known early system, PARRY (Colby, 1976), mimics the surface behavior of a paranoid schizophrenic, where again the system is not actually expected to produce utterances that relate coherently either to the way the world is or to the user's utterances. In settings in which the system is not actually expected to say anything new or useful, this kind of approach can produce reasonably plausible behavior. If we want a system that will take an active part in a goal-directed conversation about external facts, however, we need something more.

Nonetheless, the idea that a typical dialogue consists of a collection of variants on a set of simple patterns has been exploited in numerous '**natural language front-ends**,' where the user is expecting to converse with a database containing information about some specific domain. Suppose, for instance, that we want a system that can be used for interrogating a database of train times. A set of patterns such as the ones in Figure 3 would cover a large fraction of the things a user would be likely to say.

If the system is supposed to respond to users' queries by telling them about train times, the right-hand sides of the 'rules' in Figure 3 cannot just be canned phrases with slots to be filled by elements of the query. They also have to include actions that interrogate the relevant database, with the results of these queries being inserted into the response. The principle, however, remains much the same. If we know what the user is likely to say, and what he or

```
[?X my mother/father/family ?Y] ==> [tell me something about your family]
[?X my mother/father/family ?Y] ==> [you seem to dwell on your family]
[?X my mother/father/family ?Y] ==> [are you hung up on your family]
[because ?X me ?Y] ==> [is it beacuse ?X you ?Y that you came to me]
[my ?X me] ==> [what makes you think ?X you]
[I was ?X] ==> [did it upset you that you were ?X]
```

Figure 2 EMACS-ELIZA rules.

```
[when is the next train to ?Y] ==>
[do you know when the next train to ?Y is] ==>
[can you tell me the time of the next train to ?Y] ==>
```

Figure 3 Train timetable queries.

she is likely to want the system to do as a result, then a simple set of patterns will often suffice for interpreting the input (indeed, in the context of a train timetable system a single pattern such as `[?X next train to ?Y]` ⇒ `???` would cover all the patterns in Figure 3 since if the user says anything about the next train to Y he or she is likely to want to know when it is). The key difference between chatterbots that have been constructed for entertainment and practical systems based on this simple technology resides in the actions on the right-hand sides of rules. Simple substitution produces an ELIZA or a PARRY; actions that interrogate a repository of facts and rules produce a useful front end to a database.

This kind of approach is popular for spoken dialogue systems. Automatic speech recognition (ASR) software for use by arbitrary speakers is only reliable if the range of utterances that will be said is tightly constrained. Dedicated ASR systems can attain considerable accuracy if the user is prepared to train them, for example, by reading out an extended passage so that the system can adjust to the characteristics of the way the user speaks (accents, properties of his or her vocal tract, etc.). However, if a system is to be used on a casual basis by a wide range of speakers, then it will have to be provided with strong hints about what is likely to be said. Such hints often take the form of a context-free grammar (CFG), with specific actions attached to the rules of the grammar.

Associating actions with the rules of a CFG is very similar to attaching actions to the right-hand sides of rules like the ones in Figure 3. CFGs are somewhat more powerful than the simple rules given previously, although it is possible to use regular expressions to specify the patterns on the left-hand sides of these rules, in which case the range of utterances that can be compactly covered is very similar. In any case, the grammars that are used to guide ASR systems tend to be very simple since there is a trade-off between the size of the grammar and the reliability of the ASR system (many such systems allow different CFGs to be switched in depending on the state of the dialogue, thus allowing for a wide range of possible utterances in different contexts). The main advantages of using a CFG rather than a set of regular expressions is that elements of a pattern can be reused. In particular, actions can be associated with *constituents* of an utterance (e.g., when the system encounters a definite noun phrase (NP) it might try to find a referent).

This kind of approach has been used as the basis for a range of systems that respond appropriately to stylized queries about restricted domains (Allen *et al.*, 1996; Jokinen *et al.*, 2003). The question is: does the ability to answer stylised queries about restricted domains constitute evidence of 'understanding'?

Meanings, Consequences, and Actions

In general, a system that is going to perform appropriate linguistic and extralinguistic actions in response to input spoken or written language will have to be able to carry out the following set of tasks:

- It must detect the structural properties of the utterance that invite the hearer to respond in some particular way. These include the words that were produced, the order in which they occur, and the intonation contour (for speech) or typography and punctuation (for written language). A system cannot understand what someone who says '*Give it to me*' wants it to do unless it can recognize that the utterance contains the words '*Give,*' '*it,*' '*to,*' '*me*'; that they occur in the standard order for an English imperative sentence with a ditransitive main verb; and that the word '*me*' is stressed.
- It must decode the significance of these items. It is no good just knowing what the words are, what order they appear in, and where the stress falls. The system has to know what the words mean, how the surface order encodes specific relationships between word meanings, and how intonation/typography encodes the speaker's attitude to the content of the utterance.
- It must reason about what the speaker wants. To respond appropriately to an utterance, it has to think about why the speaker produced it – about

what the speaker's overall goals are and how producing this particular utterance might help achieve them.

Regarding the pattern-action rules of the previous section, detecting the structural properties corresponds to finding a pattern that fits the input text; decoding their significance is done by executing the associated pattern; and there is very little reasoning about what the speaker wants – in general, the user is expected to be either adding new information to a repository or interrogating a repository about existing information. The ability to switch to a different grammar or set of patterns depending on the history of the dialogue does provide an opportunity for responding differently depending on the context, but even here the system designer will have done the 'reasoning about what the speaker wants' in advance, rather than the system adjusting its own responses.

To make a system that displays a deeper level of understanding than these pattern-action rules, then, we will need to increase the range of surface cues that can be detected, decode the significance of this wider range of surface cues, and deepen the reasoning ability of our systems.

Increasing the range of surface cues that can be detected means writing a grammar and a set of procedures for applying that grammar to the input text. Other articles in this encyclopedia discuss the mechanisms required for recognizing the structural cues that carry the meaning – speech recognition systems, parsing algorithms, datastructures for representing lexicons, and so on. This article focuses on the construction of meaning representations and the inference processes that are applied to those representations. Note, however, that as the range of structural cues that a system can detect increases, two related problems arise:

- Wide-coverage grammars tend to derive large numbers of different analyses for a given input string. Many words belong to multiple syntactic classes or have multiple interpretations, and this can easily lead to multiple analyses of a given string. Furthermore, it frequently happens that the function of a particular phrase is underdetermined by the grammar (this is particularly true of modifiers such as prepositional phrases and relative clauses that have a range of possible attachment sites – *I saw the man in the park*, *I believed she loved me when she said that*).
- Spoken language in particular seldom obeys the norms of conventional grammar anyway. It may be possible to write a grammar that describes what a speaker of some language 'ought' to be able to say, but even if we had such a grammar it would not cover what people actually say.

The simple pattern-matching approaches of the previous section tend to be more robust in the face of these two problems than systems based on more linguistically sophisticated grammars. They cope with ambiguity by simply being unaware of it; the first available pattern that fits the input is used, and the fact that there may be many other possibilities is simply ignored. Also, ungrammatical input tends not to cause problems because the pattern is only targeted at part of the input, and hence problems with the remainder are ignored. Nonetheless, it seems likely that systems that are sensitive to the full range of structural cues will prove more flexible, and hence more likely to display 'understanding.' The remainder of this article concentrates on the kind of information that is encoded by the full range of structural cues and on the reasoning that can be based on this information. Strategies for dealing with ambiguity are discussed, but the problem of detecting fine-grained structural cues in ungrammatical input is left to other articles in the encyclopedia.

Meaning Representations

Computer systems operate by applying **transformations** to **internal states**, where there is a correspondence between internal states and the task the system is intended to perform. All computer systems do this – procedural programs, object-oriented programs, logic programs, and neural nets. There is no other way for a computer to work.

The internal state of a computer system that interprets and acts on natural language utterances has to correspond to two aspects of the task. There has to be a mapping between the structural cues in the input text and the state of the system, and there has to be a mapping between this state and a view of the external world. It must also be possible to carry out transformations to extract information that is implicit in the current state of the system – in other words, to carry out inference using it.

We start by considering the second of these mappings, between the internal state of the computer and a view of the external world. How is it possible to make a mapping from an internal state of the computer and a view of the external world?

One approach is to devise a language for describing the world and then make a mapping between states of the computer and this language, where a language is defined by a set of primitive building blocks (words and terms) and a set of rules of combination. Consider, for instance, the language of first-order logic:

Building blocks

- **Variables:** There are a set of symbols, x, y, z, x_1, x_2, ... , y_1, y_2, ... , that are designated as 'variables.'
- **Constants:** There are a set of symbols, a, b, c, a_1, a_2, ... , b_1, b_2, ... , that are designated as 'constants.' The set of constants may be extended to include arbitrary symbols as required.
- **Functions:** There are a set of symbols, f, g, h, f_1, f_2, ... , g_1, g_2, ... , designated as 'function symbols.' Each function symbol has an associated integer called its 'arity.'
- **Predicates:** There are a set of symbols, P, Q, R, P_1, P_2, ... , Q_1, Q_2, ... , designated as 'predicate names.' Each predicate name also has an associated integer called its arity. The set of predicate names may be extended to include arbitrary symbols as required.
- **Connectives:** The set of symbols &, $\vee$, $\rightarrow$, $\neg$, $\forall$, $\exists$ are designated as 'connectives.'

Rules of combination

- **Terms:** Any variable or constant is a term. If f is a function symbol of arity n and t_1, ... , t_n are terms, then $f(t_1, \ldots, t_n)$ is a term.
- **Atomic formulae:** If P is a predicate name of arity n and $t_1, \ldots, t_n$ are terms, then $P(t_1, \ldots, t_n)$ is an atomic formula.
- **Compound formulae:** If A and B are (atomic or compound) formulae, and x is a variable, then $A\&B$, $A \vee B$, $A \rightarrow B$, $\neg A$, $\exists xA$ and $\forall x$, A are formulae.

This language can be used for describing states of the external world as follows:

Denotations

- **Constants** denote individuated entities.
- **Functions** denote mappings from (N-tuples of) entities to entities.
- **Predicate names** denote sets of N-tuples of entities (so, for instance, if *brother* was a predicate name then it might include the pair of entities denoted by the constants *cain* and *abel*, the pair denoted by *romulus* and *remus*, and so on).

Truth conditions

- **Atomic formulae:** If $P(t_1, \ldots, t_n)$ is an atomic formula, and $d(t_i)$ is the entity denoted by the term t_i, then it is true if and only if the N-tuple $\langle d(t_1), \ldots, d(t_n)\rangle$ is a member of the set denoted by P.
- **Compound formulae:** $A\&B$ is true if both A and B are true, $A \vee B$ is true if at least one of A and B is true, $A \rightarrow B$ is true unless A is true and B is false, and $\neg A$ is true if A is false. If A is a formula, then let $A_{t/x}$ be the formula obtained by replacing every occurrence of x in A by the term t (there are no restrictions on how many times x appears in A: in particular, it may not occur at all, in which case $A_{t/x}$ is the same as A). Then $\forall xA$ is true if $A_{t/x}$ is true for every term t, and $\exists xA$ is true if $A_{t/x}$ is true for some term t.

This description of first-order logic glosses over some fine detail (it is important to be careful about how terms are substituted for variables in the truth conditions of quantifier formulae, for instance, and some accounts provide truth conditions for formulae containing free variables). Nonetheless, it provides a reasonable working definition of a language for describing the world in terms of individuals and relations between individuals, as long as all that matters about a relation is the set of individuals that belong to it (e.g., as long as the relation *brother* simply denotes a set of pairs of individuals).

This language has a number of useful properties:

- It is **representable** within a computer. The basic building blocks (constants, variables, function symbols, predicate letters, and logical connectives) can be mapped to unique locations in the computer's memory, and the rules of combination can be mapped to rules for building datastructures.
- It supports a notion of **consequence** that make it possible to extract implicit information from a set of formulae. This notion is expressed by a set of rules such as $\{\ldots, A\&B, \ldots\} \vdash A$ (you can infer A from any set containing $A\&B$), $\{\ldots A, A \rightarrow B, \ldots\} \vdash B$ (you can infer B from a set containing A and $A \rightarrow B$), $\{\ldots, \forall xA, \ldots\} \vdash A_{t/x}$ (you can infer $A_{t/x}$ if you already have $\forall xA$), and so on.
- The inference rules are also representable: You can write procedures that will transform a state of the computer that represents some set of formulae $\{A_1, \ldots, A_n\}$ to a state representing $\{A_1, \ldots, A_n, B\}$, where B is obtained by applying one of the inference rules to $\{A_1, \ldots, A_n\}$.

First-order logic, then, is a candidate for the language to be used for constructing meaning representations. Recall that such a language must support two mappings: one from structural cues present in natural language to formulae and one from formulae to views of the world. The formula obtained by the first mapping is referred to as a '**logical form**' for the sentence in question. The second mapping is defined by the interpretation rules for first-order logic given previously. A typical logical form is shown in Figure 4, which was obtained from (4) ($\exists X$: $\{P\}Q$, to be read as '*some X which satisfies P also satisfies Q*,' is

$$
\begin{array}{l}
\exists A : \{aspect(now, simple, A)\} \\
\quad \theta(A, agent, ref(\lambda B(speaker(B)))) \\
\quad \&\theta(A, \\
\qquad event, \\
\qquad \exists C : \{aspect(now, simple, C)\} \\
\qquad\quad \theta(C, agent, ref(\lambda D(centred(D, ref(\lambda E(cdiscourse(E)))) \ \& \ f(D)))) \\
\qquad\quad \&\theta(C, object, ref(\lambda F(speaker(F)))) \\
\qquad\quad \&love(C)) \\
\quad \&know(A))
\end{array}
$$

Figure 4 Logical form for '*I know she loves me.*'

equivalent to $\exists X(P\&Q)$, and $\forall X$: $\{P\}Q$, read as '*every X which satisfies P also satisfies Q*,' is equivalent to $\forall X(P \rightarrow Q)$.):

(4) I know she loves me.

If we want to use first-order logic as a framework for building meaning representations, we have to be able build logical forms of the kind in Figure 4 for every sentence of our natural language, and we have to be sure that these logical forms capture all the distinctions that can be made in our natural language. Suppose, for instance, that it turned out to be impossible to express the distinction between *I believe John is an idiot* and *John, I believe, is an idiot* in first-order logic (or worse, that it turned out to be impossible to express what these two sentences have in common). Then clearly this language would not be suitable as a vehicle for building meaning representations.

Compositionality

One approach to specifying the mapping between sentences of natural language and formulae of some logic involves specifying a set of rule-to-rule correspondences. This idea originated with the work of Richard Montague (Thomason, 1974) (Montague's formulation of his ideas is fairly dense, and his work is cited more often than it is actually read: Dowty *et al.* (1981) provided a slightly more digestible introduction to the key ideas).

The idea is that the system builds a meaning representation by starting with the meanings of individual words and gluing these together in ways determined by their structural relations. For this to work, natural language must obey the **principle of compositionality**, which states that 'the meaning of the whole is a function of the meaning of the parts and their mode of combination.' To put it another way, when a system is trying to work out what something means, the only evidence it has is the sequence of words that were uttered. So the only thing it can do is look up the meanings of the individual words and use the structural properties of their arrangement to decide how to put these meanings together.

The principle of compositionality is both inescapable and unworkable. It is inescapable because there is nothing but a sequence of words, arranged in a particular order and uttered with a particular intonation contour. So there is nothing but a set of parts and a 'mode of combination,' and if these do not suffice for building a meaning representation then there is nothing else to fall back on. It is unworkable because it is generally not clear what the parts are or how they are arranged. Consider (5) and (6):

(5) I keep it tied up at the bank.

(6) I am going to see to John.

(5) admits two interpretations, one in which *the bank* is the border of a river (*What do you do with your boat when you're not using it? I keep it tied up at the bank*) and one in which it is a financial institution (*What do you do with the rest of your capital? I keep it tied up at the bank*). (6) also admits two interpretations, one in which *to see John* is the purpose of my travel (*Why are you going to London? I am going to see John*) and one in which *going to* is a future tense marker (*Will you see John or Mary? I am going to see John, and then I might give Mary a ring*).

In (5) it is unclear what the parts are. In (6) it is unclear how the parts are combined to make the whole. So simply relying on sets of rule-to-rule mappings will not uniquely determine the meaning: given a sequence of words, the principle of compositionality generally produces a set of possible meanings rather than determining a single unique interpretation. We return to this question later. For now, suppose that we could construct a single meaning representation in first-order logic by examining the words and their structural arrangement. Would such a meaning representation enable a system to respond appropriately to whatever was said to it?

Adequacy of First-Order Logic

In order to respond appropriately to an utterance, a system has to be able to work out its consequences in the context in which it was produced. In particular, given two distinct but closely related utterances it has

$$\exists A : \{man(A)\}$$
$$\exists B : \{peach(B)\}$$
$$\exists C : \{aspect(now, prog, C)\}$$
$$\theta(C, agent, A) \& \theta(C, object, B) \& eat(C)$$

Figure 5 Logical form for '*a man is eating a peach.*'

to be able to distinguish between their consequences – the speaker will have chosen between them because one more accurately carries the intended message than the other, so if the system cannot tell the difference between them it will inevitably sometimes extract the wrong consequences.

It is therefore worth trying to ascertain the extent to which formulae of first-order logic can capture the import of natural language sentences. We start by considering a simple case in which it does seem to be possible to capture the meaning of a sentence of natural language:

(7) A man is eating a peach.

The logical form in Figure 5 displays many of the characteristics of a typical logical form. In particular, it mentions an 'eating event' *C*, with the other items introduced in the sentence playing named roles ('*agent*,' '*object*') with respect to that event. The notion that natural language sentences report **events** has become widespread since the work of Davidson (1967, 1980). Once we allow events to have a central role, other entities have to be linked to them as participants. Note that, there are no clear surface markers for the links between the event and its participants. It is clear that the NP *a man* is the subject of the verb phrase *is eating a peach*, but it is less obvious that he is playing the role of *agent* with respect to the eating event, as opposed to being the *actor*, the *protagonist*, the *eater*, or indeed just the *subject*.

We see here an immediate divergence from strict compositionality. The person who wrote the semantic rules underpinning the logical form in Figure 5 decided that the participants in a typical eating event play the roles of *agent* and *object*, with the (semantic) *agent* of the event denoted by the (syntactic) subject of the verb and the (semantic) *object* of the event denoted by the (syntactic) object of the verb. This is a perfectly reasonable decision, but it is difficult to argue that it is the 'right' one. Following Fillmore's (1968) analysis of the issues, there have been numerous proposals for sets of thematic roles (e.g., Bruce, 1975). Dowty (1989) provided an insightful discussion on the issues, explaining why allocating each verb its own set of thematic roles (so that '*eat*' has an *eater* and an *eatee*, and '*drink*' has a *drinker* and a *drinkee*, and so on; Pollard and Sag, 1988) is unattractive but coming up with a small universal set such as the ones originally proposed by Fillmore is extremely challenging. The key for natural language understanding systems seems to be that there is little point in providing names for thematic roles without also describing the properties of particular roles. We might, for instance, attempt to characterize a set of roles by providing '**meaning postulates**' (background information couched in the same formal language as the logical forms), as in Figure 6.

The meaning postulates (MPs) (Carnap, 1936) in Figure 6 attempt to capture the relationships between various roles (*actor*, *agent*, and *protagonist*) and then to relate the verbs '*watch*,' '*look at*,' and '*see*' by noting that they have a common core ('*see*') involving an animate entity that exercises varying degrees of control and intentionality. Note that, MPs are not *definitions*, in the sense that they provide necessary and sufficient conditions for the use of particular terms. They depict relationships that can be used to determine whether some sentence *S′* can be appropriately uttered in a situation in which some other related sentence *S* has been uttered, given what else is known about this situation ("Synonymy of two forms is supposed vaguely to consist in an approximate likeness in the situations which evoke the two forms, and an approximate likeness in the effect of either form on the hearer" (Quine, 1953)).

Relating these three verbs by saying that they depict the same kind of visual experience, but with the see-er involved in slightly different ways, lets us capture the commonalities between these verbs and also the correlation between '*see*'/'*hear*' and '*look at*'/'*listen to*.' It seems likely, then, that the decision about which thematic roles we admit to our ontology depends more on the MPs we back them up with than on any intrinsic properties of the relevant verbs. Logical forms as a whole are only useful insofar as they allow us to infer the consequences of an utterance in its context. As a corollary, parts of logical forms, such as the terms used for thematic roles, are only useful insofar as we have rules that link them to other terms.

Temporal, Modal, and Intensional Logics Similar remarks apply to the aspect marker *aspect (now, prog, C)* from Figure 5. This time the term in the logical form does derive from an explicit structural clue in the text, namely the aspect marker '*-ing*.' Again, however, there is no point in including material related to the aspect in the logical form unless we are going to back it up with MPs that exploit it.

Trying to write MPs that explain the significance of aspect markers requires us to come up with an appropriate logic of time. The basic intuition behind (7), for instance, is that an eating event has begun and has not

$$\forall X \forall Y\, (\theta(X, agent, Y)) \rightarrow (\theta(X, actor, Y) \& intended(Y,X))$$
$$\forall X \forall Y\, (\theta(X, agent, Y) \rightarrow caused(Y,X))$$
$$\forall X \forall Y \forall Z\, ((watch(Z) \& \theta(Z, actor, X) \& \theta(Z, object, Y)) \rightarrow \exists U\, (see(U) \& \theta(U, protagonist, X) \& \theta(U, object, Y)))$$
$$\forall X \forall Y \forall Z\, ((lookAt(Z) \& \theta(Z, agent, X) \& \theta(Z, object, Y)) \rightarrow \exists U\, (see(U) \& \theta(U, protagonist, X) \& \theta(U, object, Y)))$$
$$\forall X \forall Z\, (((see(Z) \& \theta(Z, protagonist, X)) \rightarrow animate(X)$$
$$\forall X \forall Y \forall Z\, ((see(Z) \& \theta(Z, protagonist, X) \& \theta(Z, object, Y)) \exists U\, (light(U) \& reflect(Y, U) \& project(U, retina(X)) \& \ldots)$$

Figure 6 General-purpose thematic roles.

yet finished. To unpack this simple intuition as a set of MPs relating eating events to times, however, we have to devise a workable view of what time is like: Are intervals sets of instants or are instants the end points of intervals? Does time branch forwards? Does it branch backwards?

This has proved extremely slippery, despite a number of efforts (Allen, 1984; Moëns and Steedman, 1988; Smith, 1991; ter Meulen, 1995). The problem seems to be that our temporal intuitions are very underdeveloped. Precise mathematical models that map time onto structures like the real numbers provide answers to questions that our basic intuitions leave unanswered (e.g., Zeno's paradoxes). Physical accounts of time make the situation even cloudier, following the development of the theory of relativity and quantum mechanics (Reichenbach, 1958). It seems best, therefore, to try to say just enough about tense and aspect to support simple everyday inferences and to accept that the idea of time that underpins our everyday language is very simple and very underspecified and admits a wide range of models.

Logical forms, then, are useless without meaning postulates to back them up. You do not know what (7) means unless you know how the agent of an eating event is involved in it, what it means to have started and not finished such an event (for which you need a theory of times and events and starts and ends), what peaches are like, and so on. Some of the meaning postulates for 'closed class items' (tense and aspect markers, determiners, and prepositions) require careful manual construction, but developing a general-purpose set of MPs for open class items by hand seems extremely unappealing. We consider how to obtain MPs for open class terms later. For now we continue to review whether first-order logic will be generally expressive enough.

We have already seen that natural language enables us, indeed almost forces us, to talk about time. Suppose we wanted to pin down what eating events are like in more detail. We would want to say things like "Before the event starts, there will be an animate being that requires energy and some organic material that releases energy when subjected to appropriate chemical processes" and "After the end of the event some or all of the organic material will have been transferred to a position inside the animate being and the process of releasing energy from this material will be under way." To describe this in a formal language, we would need MPs like the ones in Figure 7.

The first few of these just say that any eating event has an agent, an object, and a pair of start and end points, where the end is later than the start. These are fairly straightforward statements: we need to know that times can be partially ordered, but that is a very weak property and does not commit us to any particular view of time. The last two, however, talk about relationships between the agent and the object at particular times, namely that before the eating starts the object is outside the agent and after it ends the object is inside the agent. This involves a move beyond ordinary first-order logic since there is now a predicate, '*at*,' which relates a term *T* and a formula *(inside(X, Y)* or *outside(X, Y))*. This cannot be captured in ordinary first-order logic, where there is a clear distinction between terms, predicates, and formulae.

We therefore need to move to a language where formulae can occur as constituents of other formulae. One way to do this is to use a '**modal logic**,' where operators that talk about 'truth in a possible world' are added to the language. One advantage of using a modal logic is that it is fairly easy to adapt inference engines that work for ordinary first-order logic so that they work for modal logics (Moore, 1984; Wallen, 1987). As ever, the only reason we want logical forms is so that we can work out the consequences of what has been said, and for that we need inference engines. So if we can take an inference engine for first-order logic and adapt it to cope with modal logic then we will be able to carry out the inferences we need.

Several other expressions of natural languages map more or less smoothly onto modal operators. The auxiliaries '*can*,' '*may*,' '*must*,' and so on clearly talk about alternative states of affairs and hence can be

$$\forall X : \{eat(X)\}\, \exists Y(animateBeing(Y) \& \theta(X, agent, Y))$$
$$\forall X : \{eat(X)\}\, \exists Y(animateMaterial(Y) \& \theta(X, object, Y))$$
$$\forall X : \{eat(X)\}\, \exists T \exists T'(start(X,T) \& end(X,T') \& T' > T))$$
$$\forall X : \{eat(X)\}$$
$$\forall Y : \{\theta(X, agent, Y)\}$$
$$\forall Z : \{\theta(X, object, Y)\} \forall T : \{start(X, T)\} \mathrm{at}(T, outside(Y, X))$$
$$\forall X : \{eat(X)\}$$
$$\forall Y : \{\theta(X, agent, Y)\}$$
$$\forall Z : \{\theta(X, object, Y)\} \forall T : \{end(X, T)\} \mathrm{at}(T, inside(Y, X))$$
$$\ldots$$

Figure 7 What is eating like?

easily treated using modal logic. '*Know*' and '*believe*' can also be seen as dealing with possible states of affairs (if you believe some proposition *P*, then your view of the world has *P* true in it), although the mapping proposed by Hintikka (1962) and very widely taken up within artificial intelligence does have a number of problems.

Natural languages do, however, tend to contain very large numbers of '**propositional attitude**' verbs that denote a relationship between an individual and a proposition – '*want*,' '*regret*,' '*expect*', '*require*,' '*allege*,' etc. Some of these do not map at all well to modal operators, and it may be that '**intensional logics**' (Bealer, 1989; Turner, 1987) that respect Frege's distinction between the extension and intension of a term are more appropriate.

Either way, we need to extend the expressive power of first-order logic in order to deal with a large number of common aspects of natural language. We also have to allow for the fact that natural language sentences often express tendencies and defaults rather than black-and-white rules. First-order logic provides two kinds of quantification: We can say that there is something of a certain kind (*A man is eating a peach*), and we can make generalizations over every item of a certain kind (*All professors are clever*). However, natural languages provide **default** quantifiers:

(8) Most cats are lazy.

(9) Few professors work as hard as they should.

It is easy enough to extend the notation of first-order logic to allow for such quantifiers: $most(X : \{cat(X)\}, lazy(X))$. The difficulty comes in trying to propose coherent interpretations of these quantifiers and to see what sorts of inference they support. The obvious way to interpret them is to say that $most(X : \{cat(X)\}, lazy(X))$ is true if the size of the set of lazy cats is greater than half the size of the set of cats. This seems reasonable enough, but it does raise a number of questions:

- Is 50% actually the right threshold, or does *most cats* mean something more like 75%? If (9) had been *Very few professors work as hard as they should*, would this mean that 95% of them do, or 98%, or . . . ? Picking an arbitrary threshold seems inappropriate, and picking the right threshold seems impossible.
- What happens if the set in question is unbounded? *Most cats are lazy* does not just mean that most of the cats born on or before April 1, 2005, are lazy; it means that most of the cats that will ever be born are lazy. But since this is an unbounded set we cannot really talk about its size (the situation is worse for a sentence like *Most prime numbers occur in clusters*, whose truth or falsity depends on the distribution of subsets of an infinite set).
- Rules like (8) can be used with a simple statement of fact like *Splodge is a cat* to support the conclusion *Splodge is lazy*. The ways that people actually use these rules tend not to fit the idea that *most cats* means *more than half the set of cats* very well.

There have been a number of attempts to deal with quantifiers of this kind by appealing to cardinalities of sets (Barwise and Cooper, 1981) or by using default logics (McCarthy, 1980; Reiter, 1980). Either way, the presence of words such as '*most*' and '*few*' requires an expressive power that is not available in standard first-order logic.

This extra expressive power is also useful when we are trying to characterize open class words such as '*cat*' and '*table*.' As noted previously, we cannot in general provide sets of necessary and sufficient conditions for the use of everyday words such as '*cat*' and '*table*.' What we have instead are '**semantic traits**' (Cruse, 1986) – properties that *most* items of the kind in question possess: $most(X : \{table(X)\}, hasFourLegs(X))$, $most(X : \{table(X)\}, hasFlatSurface(X))$, $most(X : \{table(X)\}, rigid(X))$ etc. The use of default logic or generalized quantifiers for dealing with explicit use of words such as '*most*' and '*few*' also allows us to express the meaning postulates for everyday concepts in a '**defeasible**' manner, thus allowing, for instance, for various kinds of nonstandard tables (ornamental tables that are not designed

to have items put on them, inflatable camping tables, etc.).

Dynamic Logics The final problem with first-order logic is that it does not provide anything corresponding to the use of referring expressions in natural language. Natural languages provide a range of devices whose primary aim is to pick out known individuals. These include proper names ('*Allan Ramsay*'), definite NPs ('*the author of this article*'), pronouns ('*he*'), and referential tense markers ('*he* ***had*** *been thinking about corpus-based approaches*'). The nearest thing that first-order logic has to these is the use of constants, but there is a sharp distinction between the constants of first-order logic and the referring expressions of natural language: constants point to individuals by stipulation, whereas referring expressions point to individuals by describing them. To interpret a formula of first-order logic we have to know the mapping between constants and individuals. This mapping is arbitrary and is simply stipulated: you either know it or you do not. Referring expressions, on the other hand, provide information that should enable a properly informed hearer to find the entity in question. The NP '*the only person to have scored a double century in postwar Irish cricket*' provides enough information about the person in question to enable any interested party to track down the individual being referred to.

Referring expressions are used to **anchor** an utterance in a context so that it provides new information about the entities in that context. To do this, there must be exactly one thing in the context that fits the description. If there is not anything at all that fits the description, then the utterance simply does not provide any information: uttering '*The present king of France is bald*' at the present time says nothing about what the world is like because there is no present king of France. If more than one thing fits the description, the utterance provides no useful information since it is not clear which of the potential referents the utterance is concerned with: '*Two masked men came into the bank. The masked man pointed a gun at the cashier while the masked man carried out the cash.*'

To mimic the function of referring expressions within a formal language, most theories include terms which contain descriptions to be satisfied. Interpreting an utterance then involves two stages: start by resolving the referring expressions, using information that is available in the current context (discourse state, situation, slate, (etc.) and then add the consequences of the resulting anchored logical form to the context. Meanings are thus viewed dynamically, as relations between contexts. A given sentence will produce different effects in different contexts, partly because the anchoring process will be different in different contexts and partly because the resulting anchored form will have different consequences in different contexts.

This is not just because the referring expressions will point to different things in different contexts. Clearly, '*the hill we walked up yesterday*' will denote one thing if you say it today to your girlfriend and a different thing if a tour guide in the Andes says it next year to a walking group. In both cases, the addressees use their knowledge of their recent activities to find a single entity that fits the description, and that is all there is to it. But the conventions around referring expressions can be exploited to introduce entities into a conversation by '**accommodation**' (Sperber and Wilson, 1986), and they can also be used in contexts in which you know there must be exactly one thing that satisfies the given description, even if you know nothing else about it – you can meaningfully say '*I always feel better when I see* ***the first snowdrops of Spring***' because you know that every year there is some earliest occasion when there are snowdrops to be seen, even though you may have no idea when or where it will be this year.

We thus, need to extend the language we use for logical forms to include something corresponding to the use of referring expressions in natural language. There have been numerous proposals for such extended languages, including file change semantics (Heim, 1983), discourse representation theory (Kamp, 1984; Kamp and Reyle, 1993), situation semantics (Barwise and Perry, 1983), dynamic predicate logic (Groenendijk and Stokhot, 1991). The details of these theories vary, but the key observation that logical forms include descriptions that have to be anchored before their consequences are added to the current context is generally shared.

Ambiguity

Whatever formalism we choose for meaning representations, the structural properties of the text do not in general determine a unique meaning representation. We have already seen examples of lexical and structural ambiguity in (5) and (6), and it is extremely easy to find more. To make matters worse, there are cases in which there are clearly multiple readings but where there is no apparent lexical or structural cause:

(10) Someone is mugged every five minutes in New York, and he's getting pretty sick of it.

Most people are momentarily taken aback when they first encounter (10) and have to think about it for a second. When you read the first part, *someone is mugged every five minutes in New York*, you

$$
\begin{array}{l}
\forall A : \{five(A, \lambda B(minute(B)))\} \\
\quad \exists C : \{one(C)\} \\
\quad\quad \exists D : \{aspect(now, simple, D)\} \\
\quad\quad\quad \theta(D, object, C) \\
\quad\quad\quad \&during(A, D) \\
\quad\quad\quad \&mug(D) \\
\quad\quad\quad \&in(D, ref(\lambda E(named(E, \text{'New York'}))))
\end{array}
$$

Figure 8 Primary reading of (10).

construct an interpretation like Figure 8, in which *every five minutes* **outscopes** *someone* (i.e., where for every set of five minutes, *five* $(A, \lambda B(minute(B)))$, there is someone C who is mugged in New York). When you hear the second part, *he is getting pretty sick of it*, you realize that some earlier part of the discourse must have mentioned a single male individual for *he* to refer to. This forces you to rethink the interpretation of (10) to make *someone* outscope *every five minutes*.

It is hard to see a lexical or structural source for the ambiguity of (10). Dowty *et al.* (1981) do analyze an example rather like this one by proposing alternative, rather forced, syntactic analyses, and certain categorial approaches make it possible to obtain this ambiguity by following different derivation paths. However, most grammars assign a single structural relation between *someone* and *every five minutes* (there is also an attachment ambiguity involving *in New York*, but that is not the key point here). (10) suggests that the structural cues '**underdetermine**' the meaning – that even when we have examined as closely as possible the surface form, there may still be some doubt about what was meant.

What can we do if the structural cues do not give us a unique meaning representation? Sometimes inspection of the alternatives makes it possible to rule out some options because they seem to make no sense, either in isolation or when we try to anchor them:

(11) I saw the man with a big nose.

(12) I saw the man in the park.

The interpretation of (11) that attaches *with a big nose* to *saw* can be ruled out because noses are not the kind of thing you can use for seeing with. The choice between attaching *in the park* to *saw* or to *man* in (12) can be determined when our system is trying to anchor the logical form: if there are two men, one of whom is in the park, then it should attach *in the park* to *man* since the NP *the man in the park* will uniquely identify one of the men, whereas *the man* will not; if there is only one man, then it should attach *in the park* to *saw* since *the man* will uniquely identify the individual, and the extra information is not needed for anchoring (Hirst, 1987).

In many cases, however, the choice is less clear-cut. In such situations, there are two possibilities: The system can make an arbitrary choice (or a choice based on statistical evidence) and backtrack when it realizes that it has got it wrong, or it can decline to make a choice. It is clear that people do sometimes make a concrete choice and then backtrack: the fact that most people report doing a double-take when confronted with (10) shows that they made a choice and then realized that it was the wrong one. It often happens, however, that two interpretations lead to the same conclusions. Consider (13) (the same as (12), but with *a man* instead of *the man*):

(13) I saw a man in the park.

Most of the time, you only see things that are quite near to you, unless they are extremely large or you are using an optical device such as a telescope. Since men do not tend to be extremely large, and there is no mention of a telescope in (13), it is reasonable to assume that the man was not very far away from the speaker. In which case, it is likely that the speaker, the man, and the seeing event were all in the park at the time: if the seeing took place in the park, and the man was not far away, then he was probably in the park, and if the man was in the park when he was seen from not far away then the seeing was probably in the park. It does not matter.

This notion was explored by Blackburn *et al.* (1997), who suggested the 'most informative' interpretation is the best. This can be found by looking for the one that has the largest number of consequences. This is a rather tricky notion since every proposition has an infinite number of consequences, so what is actually required is the one with the largest number of *nontrivial* consequences. This can be carried out by looking for models rather than for consequences (Baumgartner and Kühn, 2000; Ramsay and Seville, 2000), where model generation is a variant of automated reasoning that has close correlates with observations from psychological studies (Johnson-Laird, 1983).

Whatever we do about ambiguity, however, we have to accept that sometimes our system will make the wrong choice. Unless there is very strong evidence for or against particular interpretations, it can often be a good idea to carry the choices forward unresolved in the hope that (a) the required information will turn up later, (b) the alternatives may have the same consequences, or (c) the task being carried out does not require a choice to be made anyway (machine translation systems often try to exploit a similar strategy: the French sentence *J'ai vu un homme dans le parc* has exactly the same ambiguity as the English

sentence *I saw a man in the park*, so a system that carries out the translation like this is in no danger of choosing the wrong interpretation).

Corpus-Based Approaches

From the previous discussion, it is apparent that systems for understanding natural language must be able to represent the external world, in the sense that there is a mapping between (some subset of) their internal state and ways that the external world might be. Such a mapping is generally obtained by producing a one-to-one mapping of internal data-structures to formulae of some suitable language and relying on the standard semantics of that language to provide the mapping to states of the external world.

The previous discussion considered some of the constraints on such a language and suggested that it would at least need to extend standard first-order logic by allowing for modal and intensional operators, default rules, and referring expressions. However, there is no point in having such a language for expressing logical forms unless they can be linked to general knowledge about the world. A system will at least seem to understand what you say to it if it can react appropriately, but in order to react appropriately it has to have knowledge beyond the literal propositional content of what has just been said to it.

When an adult human 'reacts appropriately' to an utterance, he or she will bring a lifetime's knowledge about the world to bear – commonsense knowledge about the basic physics of the world, social and societal knowledge, technical and academic knowledge, and so on. To understand a simple pair of sentences such as '*We went out for a meal last night. The waiters were so rude that we decided not to leave a tip*' requires huge amounts of background knowledge – that when you go out for a meal you usually go to a place that employs people who find out what you want to eat and then bring it to you, and that these people are generally very badly paid and rely on extra payments by customers to supplement their wages, but that you can decide not to make these extra payments if you do not feel that you have been well treated (Schank and Abelson, 1977).

Providing a computer system with all this knowledge seems to be a very daunting task. Do we have to provide it all manually, telling the computer everything it needs to know, or can at least some of it be acquired automatically?

For a system that needs to display a detailed level of understanding about some restricted domain, it is feasible to specify everything that the system needs to know by hand. If, for instance, we want a speech-driven interface to an e-mail system, it makes sense to tell it that e-mail messages generally contain information about who sent them, what they are about, and when they were sent, and that mail tools generally annotate messages to indicate whether they have been read and, if so, whether a reply has been sent. The amount of knowledge required for even a simple domain like e-mail handling often turns out to be surprisingly large, but it is usually possible to encode it manually. The advantage of doing it this way is that we can be sure that the rules we have written are correct, and cover the headings that need to be covered, so that we have some confidence that the system will indeed know what to do when a user says '*Do I have any new messages from Adam about the DUMAS workshop?*'

For task-oriented systems, then, it is often sensible to hand code the background knowledge that will be used to enable the system to respond. For more open-ended systems, this may not be possible.

There have been a number of attempts to develop large-scale knowledge bases that can be used for, among other things, open-ended natural language understanding systems. The CYC project (Lenat and Guha, 1990) is a continuing attempt to produce a very large knowledge base of this kind. The CYC project has been running for approximately 15 years (similar to the time that a typical human adult spends acquiring his or her own knowledge base), and has consumed many person-years of effort, in order to encode a substantial amount of knowledge in a language that is an "augmentation of first-order predicate calculus (FOPC), with extensions to handle equality, default reasoning, skolemization, and some second-order features" (http://www.cyc.com/cyc/technology/whatiscyc_dir/howdoescycreason #cyc1) (in other words, in a language possessing many of the characteristics outlined previously). WordNet (Fellbaum, 1998) is a similar attempt to hand code large amounts of information about relations between lexical items, although here the vast majority of the information deals with hypernym/hyponym (superset/subset) relations, mainly between nouns.

These projects, and others like them (Johnson *et al.*, 2003), show that you *can* produce very large knowledge bases, but only if you are prepared to put in very large amounts of effort. Even so, many of these projects only encode subset/superset relations, which are unlikely to be adequate for filling in the gaps in natural language discourses.

Instead of hand coding the required knowledge, using some fairly awkward formal language for the task, it is tempting to try to extract it automatically.

To do this, of course, there has to be an existing repository from which it can be extracted. There is now a very large repository containing huge amounts of information that has been hand coded in natural language (mainly English), namely the Web. It is therefore very tempting to try to use machine learning/data mining techniques to convert this knowledge into something more amenable to processing by machine.

In order to decide what sorts of data mining techniques are appropriate for this task, we have to decide where in the Web we are going to search, and we have to decide what sort of information we want to extract.

- **Where in the Web?** The Web as a whole is unstructured, and the information it contains is unreliable (sites propagating conspiracy theories and alternative medical practices) and highly idiosyncratic (many Web pages contain personal details of individuals and their families and hobbies). We therefore have to choose whether to trawl the entire Web for whatever we can find, and accept that much of it will be unreliable, or whether it would be better to concentrate on a few well-informed sites such as on-line encyclopedias (e.g., Wikipedia (http://en.wikipedia.org)) or dictionaries.
- **What information?** Since most information on the Web is still encoded just in natural language, to extract it we need a natural language understanding system. This is problematic: if we had a reliable high-performance natural language understanding system, we would not need to trawl the Web for the knowledge required by reliable high-performance natural language understanding systems. The vast majority of the information that is obtained from the Web, then, must be extracted by using systems that do not fully understand the text they are reading.

For this reason, most automatic knowledge acquisition concentrates on information that can be obtained by looking at cooccurrence patterns. By looking for 'meaningful' cooccurrence patterns (e.g., looking for nouns that occur as the heads of the objects of identical verbs) it is possible to extract sets of words with 'similar' meanings (Pantel and Lin, 2000). This kind of information can be used internally within natural language understanding systems or to supplement the hand-coded information provided by knowledge bases such as CYC and WordNet.

Inference

No matter how much knowledge we provide, and how rich our logical forms are, our systems will not display understanding unless they can carry out inference. Understanding involves appropriate directed action – either linguistic action (answering a question) or extralinguistic action (reading out a list of e-mails in response to a query such as '*Do I have any new messages?*'). For a computer to carry out inference, it has to be able to apply inference rules that extract implicit information from its current state. There are essentially two approaches to this task: structural and statistical inference.

Structural Inference

Structural inference involves writing sets of rules that match patterns in the formulae of some formal language and produce new formulae when they are triggered. An obvious example of such a rule is the classical rule of *modus ponens*: If you have one formula that has the form $P \rightarrow Q$, for some pair of subformulae P and Q, and another one that has a form that matches P, then you can infer Q.

Modus ponens would allow you to infer '*rain*' from '*people are carrying raised umbrellas*' → '*rain*' and '*people are carrying raised umbrellas,*' *poor(John)* from *student (John)* → *poor(John)* and *student(John)*, and so on.

Numerous sets of structural rules have been proposed, from Aristole's syllogisms through the rules of natural deduction to a range of uniform rules designed explicitly for use within computational inference engines (Davis and Putnam, 1960; Robinson, 1965). These rules are designed to be sound (any conclusions that can be produced by using them are safe) and as far as possible complete (if something is guaranteed to be true given a set of hypotheses, then the rules will lead to a proof). Unfortunately, as the rules become more complex it becomes more difficult to choose a good order in which to apply them. In particular, once we start allowing default rules and arbitrary quantification over propositions and properties, as suggested by the previous discussion, it turns out that no inference engine can be guaranteed to find a proof if one exists, let alone to report when there is no proof to be found.

Statistical Inference

The structural rules of the previous section cannot cope with cases in which the connection between two propositions is inherently probabilistic. This may occur in two situations. First, the text may contain an ambiguous word or syntactic structure, and it may be possible to use statistical evidence to choose between the alternative readings. For instance, we may have managed to collect information about the relative frequency of the two main senses of the word '*bank*' in articles that also mention words that are similar to the word '*loan*' (in the sense outlined

previously). If we have such statistical information about word frequencies, we may use it to choose the appropriate meaning for '*bank*' in '*I asked the bank for a loan*' or for deciding on the appropriate attachment for the prepositional phrase in '*I saw the man with a big nose*.' Second, the background knowledge triggered by an utterance may itself be statistical. If you know that 90% of white cats are deaf and that 70% of deaf cats get run over in their first year of life, then the sentence '*We just got a white kitten*' might prompt you to expect that the animal in question is unlikely to live very long.

Most attempts to exploit probabilistic reasoning within computational systems depend on Bayes's theorem, which aims to determine how likely some conclusion is given a body of evidence. Bayes's theorem relies on the observation that the probability of outcome O given some body of evidence E, written $P(O|E)$, can be obtained by dividing the likelihood that O and E will both happen by the probability that E will happen regardless of whether O also does (in other words, the probability of O given E is the proportion of occurrences of E that are accompanied by occurrences of O):

$$p(O|E) = p(O\&E)/p(E)$$

However, we can also obtain

$$p(E|O) = p(E\&O)/p(O)$$

by the same reasoning, and then, since $p(O\&E) = p(E\&O)$, we can get

$$p(O|E) = p(E|O) \times p(O)/p(E)$$

This rule can be combined with the rule that says that the probability of two propositions, E_1 and E_2, both occurring is the product of their individual probabilities

$$p(E_1\&E_2) = p(E_1) \times p(E_2)$$

to produce

$$p(O|(E_1)\& \ldots (E_n)) = \frac{p(O) \times p(E_1|O) \times \ldots \times p(E_n|O))}{p(E_1) \times \ldots \times p(E_n)}$$

This rule seems to provide a mechanism for combining probabilities. The problem is that $p(E_1\&E_2) = p(E_1) \times p(E_2)$ only holds if E_1 and E_2 are independent of one another – if $p(E_1|E_2) = p(E_1)$ and vice versa. This almost never happens when there is a causal connection between the evidence and the relation, so applying Bayes's theorem for calculating the probability of some outcome is always a dangerous thing to do (its proper function in statistics is for investigating independence: If Bayes's theorem *fails* for some set of observations, then you can conclude that they are *not* independent).

A range of mechanisms for combining probabilities have been proposed (e.g., Dempster–Shafer theory of evidence), but they generally fall foul of similar constraints (Voorbraak, 1991). Similar problems arise when you try to apply rules involving qualitative judgments (Shortliffe, 1976), and things get even worse when you need to combine probabilistic and qualitative rules. The problem is that most techniques for combining numerical 'truth values' depend on assumptions of independence that very seldom hold so that when individual truth values are combined, the results are extremely unreliable. One way out of this is to use multilayered neural networks (Rumelhart *et al.*, 1986), where the arithmetic for combining individual truth values is locally adjusted during the learning process to take account of correlations and anticorrelations between atomic propositions. Even here, though, it is extremely difficult to represent quantification, and it seems likely that hybrid reasoning systems that use standard structural rules to determine *what* follows from a given starting point and statistical rules to determine the *strength* of the evidence will be the best way forward (possibly by embodying the degree of belief in some proposition as a '**label**' (Gabbay, 1996)).

Summary

When could you say that a computational system understood natural language? If it passed the Turing test you would be hard-pressed to say that it did *not* understand what was said to it, and it seems impossible to devise any more concrete demonstration than that.

Several versions of the Turing test have been set as competitions in recent years – the Message Understanding Competition (MUC; www.itl.nist.gov/iaui/894.02/related_projects/muc/) and Text Retrieval Competition (TReC; www.trec.nist.gov/pubs.html) series require systems to answer questions posed in natural language where the answer is contained somewhere in a substantial body of text. The Loebner prize directly requires systems to pose as human beings and take part in open-ended dialogues. All these competitions pose restricted versions of the Turing test, and it is possible to argue that the systems that perform well at them use tricks that exploit the restrictions (e.g., some systems that performed well in the MUC series depended very heavily on recognizing proper names, which were important in the context of some of the early competitions but are less useful in

less restricted contexts). Nonetheless, as the tasks set in such competitions become more general, the systems that perform well in them will become ever closer to displaying understanding.

The systems that perform well in recent competitions tend to have the general architecture outlined previously. Structural cues are used for building a detailed meaning representation of the input question, and then general-purpose inference mechanisms are deployed to find an answer to that question. Systems that perform well in the MUC/TReC series tend to be good at hunting through large bodies of text for segments that contain relevant-looking material, exploiting the techniques discussed previously. As these competitions move from '*who*'/'*what*' questions to '*why*'/'*how*' questions, however, it will become important to be able to reason in-depth about source text rather than simply looking for relevant chunks. As this happens, it seems likely that constructing meaning representations from structural cues will come to be seen as a fairly minor element of understanding. Having a large body of knowledge and being able to reason about it will be the key to demonstrating understanding.

Natural Morphology

W U Dressler, Universität Wien, Wien, Austria

© 2006 Elsevier Ltd. All rights reserved.

Natural morphology, as based on an integration of concepts of markedness and of natural phonology, was founded in 1977 by W. Mayerthaler, W. U. Dressler, and W. U. Wurzel, in order to account for what is more or less natural among comparable morphological phenomena. It consists of three subtheories (Dressler *et al.*, 1987; Kilani-Schoch, 1988; Dressler, 2000; Kilani-Schoch and Dressler, 2005). The first subtheory of universal markedness, or system-independent morphological naturalness (Mayerthaler, 1981), is a preference theory (cf. Dressler, 1999). It establishes deductively the degrees of universal preferences on a restricted number of naturalness parameters. Here naturalness does not refer to any global or overall preference, but to what is universally preferred on one given parameter. Parameters and their preference degrees are deduced from semiotic and cognitive bases. The most important parameters are as follows:

1. The parameter of iconicity: a morphosemantically marked category, compared to an unmarked category, is expressed preferentially by a longer form. Thus, among English plurals, suffixation (as in *fife* + *s*) is most iconic, modification (as in *feet* vs. the unmarked singular *foot*) is less iconic (since it involves only a change), and the plural *fish* is noniconic (no change).
2. The parameter of morphosemantic transparency: full transparency means fully compositional meaning, as with most inflectional meanings. For example, the meaning of *fife* + *s* combines the meanings of *fife* and of plurality. Among compounds, *blue* + *berry* is more transparent than *straw* + *berry* is because *blue* contributes more to the meaning of the whole compound than *straw* does.

Natural Morphology

W U Dressler, Universität Wien, Wien, Austria

© 2006 Elsevier Ltd. All rights reserved.

Natural morphology, as based on an integration of concepts of markedness and of natural phonology, was founded in 1977 by W. Mayerthaler, W. U. Dressler, and W. U. Wurzel, in order to account for what is more or less natural among comparable morphological phenomena. It consists of three subtheories (Dressler *et al.*, 1987; Kilani-Schoch, 1988; Dressler, 2000; Kilani-Schoch and Dressler, 2005). The first subtheory of universal markedness, or system-independent morphological naturalness (Mayerthaler, 1981), is a preference theory (cf. Dressler, 1999). It establishes deductively the degrees of universal preferences on a restricted number of naturalness parameters. Here naturalness does not refer to any global or overall preference, but to what is universally preferred on one given parameter. Parameters and their preference degrees are deduced from semiotic and cognitive bases. The most important parameters are as follows:

1. The parameter of iconicity: a morphosemantically marked category, compared to an unmarked category, is expressed preferentially by a longer form. Thus, among English plurals, suffixation (as in *fife* + *s*) is most iconic, modification (as in *feet* vs. the unmarked singular *foot*) is less iconic (since it involves only a change), and the plural *fish* is noniconic (no change).
2. The parameter of morphosemantic transparency: full transparency means fully compositional meaning, as with most inflectional meanings. For example, the meaning of *fife* + *s* combines the meanings of *fife* and of plurality. Among compounds, *blue* + *berry* is more transparent than *straw* + *berry* is because *blue* contributes more to the meaning of the whole compound than *straw* does.

3. The parameter of morphotactic transparency: the most natural forms are those for which there is no opacifying obstruction to decomposability. Thus the singular base is easier to recover in *fife* + *s* than it is in *wive* + *s*, for which an opacifying, lexically restricted morphonological rule intervenes.
4. The parameter of binarity: binary morphological relations are preferred to ternary or *n*-ary ones. Thus compounds consisting of two members are most preferred, followed by ternary compounds with a structure that can be split into two binary relations, as in *three-star general*, meaning a general who has (binary relation) three stars (binary relation) on his shoulders. Truly ternary compounds such as *blue–white–red* (the French flag) are exceptional.
5. The parameter of optimal shape: the optimal shape of a word has the extension of one metrical foot (whereby, due to binarity, bisyllabic words are preferred); the optimal shape of an affix is one syllable.

The second subtheory of typological adequacy (cf. Dressler, 1985: 337–348), inspired by Skalička's theory (1979) of ideal language types, has reinterpreted these ideal constructs as sets of consistent responses to naturalness conflicts. Since a given language cannot limit itself to the most natural options on all universal parameters, naturalness on certain parameters must be, so to say, sacrificed for greater naturalness on others. Thus, the agglutinating type, as best represented by Turkish morphology, is very natural on the parameters of iconicity and transparency, but not on the parameters of binarity and optimal shape of words, because words are typically longer than one metrical foot and contain more than two morphemes. The inflecting-fusional type, as represented by conservative Indo-European languages, is more natural on parameters 4 and 5 than on parameters 1–3.

The third subtheory of system-dependent naturalness, or language-specific system adequacy (Wurzel, 1984), accounts for what is normal within the morphology of a language, although it may contradict some universal morphological preference (of the first subtheory). The most important concepts are productivity, default, and morphological (especially inflectional) class (cf. Dressler, 2004).

In language acquisition, young children follow universal preferences more than adults do, since these preferences are not yet curbed by an extensive knowledge, and thus by system adequacy, of a specific language. Relatively early, children are sensitive to typological characteristics of the language they acquire (cf. Bittner *et al.*, 2003). In diachrony, morphological changes that initiate within morphology tend to result in more morphological naturalness, which is not the case with contact-induced change or when syntactic or phonological patterns or rules are morphologized (cf. Dressler, 2003).

Natural Phonology

B Hurch, University of Graz, Graz, Austria

© 2006 Elsevier Ltd. All rights reserved.

General Characteristics

Natural Phonology (henceforth NatPhon) is a theory developed by David Stampe in the late 1960s (as in Stampe, 1969) (much of the original literature had circulated and remained unpublished), with a first point of culmination in his dissertation (1973b) and a parasession of the Chicago Linguistic Society in 1974 (Bruck *et al.,* 1974), as well as Patricia Donegan's dissertation in 1979. The most thorough presentation of the theory was published by Donegan and Stampe (1979). The term *natural* refers to the view that the forces governing phonological systems, alternations, phonological change, and phonological behavior in general are inherent to the limitations of human capacities of speech production and auditory perception. The dual meaning of the word *phonology* as a scientific discipline and as the specific human knowledge/capacity is mediated insofar as the former is nothing but a direct reflection of the latter.

One of the early observations by Stampe comes from language acquisition (Stampe, 1969), namely that children obviously apply different and additional processes to those from adult phonology, processes the children seemingly never have actively learned. Analogously, the same holds for aphasic varieties, where it would be difficult to claim that the speech of aphasics is characterized by a constantly more highly elaborate cognitive effort than is normal speech; cf. also other external influences that alter a given phonology and where the application of additional processes can hardly be explained by a model in which the application of a process raises the complexity of a derivation.

NatPhon is not a formal theory in the sense that formalisms themselves are considered a calque of formal restrictions of mental operations, but it is as much subject to formalizations as any other theory. A good deal of formalization in the framework of Optimality Theory can also be considered as directly corresponding to processes in NatPhon. The difference from classical and post-classical generative phonology is not so much to be sought in questions of formalizations, but rather in the status that formalizations, as opposed to functional approaches, have in grammatical theory.

A frequent misunderstanding concerns the relation of naturalness and a rather abstract notion of optimization to systems. Natural processes are antagonistic in nature, i.e., they may give opposing results in different contexts. Any specific auditory, and especially any specific articulatory, difficulty can have more than one possible resolution. Finally, the dichotomy of auditorily and articulatorily motivated changes interact to locally avoid a specific difficulty or non-preferred constellation, but – as in any other dialectic theory – naturalness is never claimed to be an evaluation device for *systems*. Each phonological system is as 'natural' as any other; every single phonology responds to the needs of its users in the same adequate way as any other phonological system. Natural phonology takes up traditional, pre-structuralist knowledge, combining it with modern advances in linguistic research.

Specific Concepts

Phonology and Morphophonemics

NatPhon advocates a sharp distincion between phonology and morphophonemics. Only phonology (including prosody) is *natural* in the above sense, morphophonemic alternations express grammatical relations. Phonologically motivated sound substitutions are termed processes, morphophonemic alternations are called rules. Alternating forms such as Ger. [ʀɑ·t] vs. [ʀe·dɐ] *Rad* vs. *Räder,* 'wheel, SG vs. PL' show both substitution types: the final devoicing of the former is a process, the umlauting of the latter a rule. This is not just a difference of definition, but instead we are dealing with two ontologically different phenomena, and it is necessary to stress this argument, as mostly formal oriented theories do claim that these two types hold the same ontological status, differing only in the location in the grammar (cf. Donegan and Stampe, 1979). Processes always apply when the phonological context is met, but the application of rules depends on lexical specifcations and/or grammatical domains. Processes thus are automatic, rules are not. Processes interfere in second language phonology, rules do not. Thus, speakers of German do apply final devoicing when talking English, but they never apply the German rules of umlaut, etc. Further, processes, because they are natural, reflect inborn restrictions of the human articulation and/or perception and need not be learned and thus are restrictions the speaker imposes on his language, whereas rules are restrictions the language imposes on the speakers (Donegan and Stampe, 1979) and have to be learned in language acquisition.

Morphophonemic rules (like the above quoted example from German umlaut) are petrifications of older phonological processes, which became opaque through morphologization. As important historical changes are gradual, rules may show remnants of phonological naturalness, and the former phonological character may be recognizable to varying degrees. In derivation, morphophonemic rules precede processes.

Fortitions and Lenition

A natural process is defined by Stampe (1973b: 1) as a "mental operation that applies in speech to substitute, for a class of sounds or sound sequences presenting a specific common difficulty to the speech capacity of the individual, an alternative class identical but lacking the difficult property." Processes responding to auditory restrictions are called fortitions, those responding to limitations of articulation are termed lenitions. Fortition, thus, is a cover term for all centrifugal tendencies in which an acoustic image of a sound or sound sequence (either in isolation or in relation to other sounds) is sharpened, the perceptual distance between sounds enlarged, or the sequencing improved. Lenitions, on the other hand, embrace all assimilatory and centripetal tendencies which make pronunciation less expensive. Centripetal tendencies do normally have a negative effect on perceptual clarity. The basic order in derivation is *fortition first – lenition last*. Both fortitions and lenitions strongly depend on prosodic variables (e.g., a preference for fortitive processes in prosodically strong positions and for lenitions in weak contexts).

Paradigmatic and Syntagmatic

Processes can work in two different ways, paradigmatically and syntagmatically. For NatPhon, a given phonological system is the result of the paradigmatic functioning of processes. In her seminal dissertation, Donegan (1978) has exemplified this view in the working of vowel systems: a limited number of processes, justifiable on general grounds, systematically limits the phonatory capacities of the oral tract in order to select preferred points of vocalic articulation, thus producing vowel systems. Syntagmatic processes derive phonetic realizations from underlying representations. Paradigmatic operations are fortitive in character, and they may both be context-free and context-sensitive; syntagmatic ones may either be fortitive or lenitive and are always context-sensitive. This is the only way in which we can conceptualize a language-specific phonology as a harmonic entity comprising both the system and its concrete realization.

Naturalness and Markedness

The concept of naturalness has often been paralleled yet both confused with and substituted by markedness. And indeed the effect of a paradigmatic process devoicing obstruents at first sight is equivalent to a markedness relation that postulates voiced obstruents to be more marked than unvoiced obstruents, or an implicational law that states that the existence of voiced obstruents implies the existence of voiceless obstruents. It was specifically proponents of Natural Morphology who advocated assuming markedness to be the driving force of phonology in analogy to their concept of describing morphological regularities (Wurzel, 1984). Stampe (1973a) showed that the concept of antagonistic processes is both able to explain underlying representations and surface realizations, as well as historical change, and that what surfaces as markedness in phonology is a direct reflex of natural processes.

Prosody

Prosody is as integrally part of phonology as the segmental aspect, it merely deals with a different side of the same phenomenon. Prosodic units are the result of processes of human temporal behavior and the realization of specific linguistic and segmental phonological units in time. Each prosodic unit stands in a double relationship as the organizational procedure of smaller units and itself being an element of a hierarchy directed upward. And both faces of the coin determine structural aspects. Although we do not have convincing arguments to assume the syllable to be part of the *lexical* representation of words, it is considered to be the central unit for realizing segments in time and of grouping segments together so as to make them manageable on the level of prosodic feet. Segments thus to some extent determine the structure of syllables and at the same time are determined by it (e.g., the inherent sonority of segments determines the nucleus, hence structural aspects, which in their turn determine voicing in specific non-nuclear positions). Virtually the same holds true for accent: on the one hand, accent organizes syllables into feet, on the other, it is the result of the application of prosodic processes of accentuation which create accent patterns to which the syllables are mapped. Again, certain syllabic positions are the material basis on which accent works, and they are themselves structurally dependent from their prosodic context.

The specific importance of prosody in NatPhon has also been outlined by its role in typology. An interesting study by Donegan and Stampe (1983) shows that

it is probably rising and falling word accentual patterns that condition the setting of important typological variables on other prosodic, morphological, and syntactic grounds.

Related Proposals in Phonology and Outside Phonology

In the beginning, NatPhon was sometimes confused with *Natural Generative Phonology* (NGP), a theory intimately associated with the names of Joan (Bybee) Hooper (1976) and Theo Vennemann (1974). NGP contributed to the abstractness debate of the late 1970s and early 1980s by postulating a *naturalness condition* which severely constrains the arbitrariness of underlying representations by linking them directly to existing suface patterns.

Within the development of ideas referring directly to NatPhon, there should be mentioned at least two schools: cognitive phonology as outlined by Nathan (1996, 1999) and the proposal by Dressler (1985, 1996). Dressler's main issue is that there has to be established a concept of naturalness across the components based on general semiotic parameters on which he maps the Stampean concept of phonetically conditioned naturalness. Nathan seeks to parallel a concept of phonological space with organizational principles developed in Cognitive Grammar, such as prototype theory, mental images, and so on.

The radical difference between NatPhon and generative phonology has somewhat been attenuated with the rise of Optimality Theory (Hurch, 1998). Although the latter apparently postulates a radical change in questions of form and substance, it more thoroughly refers to traditional knowledge and also reduces the arbitrarity of analyses by requiring constraints to be motivated on independent grounds.

Natural Semantic Metalanguage

C Goddard, University of New England, Armidale, Australia

Introduction

The term 'natural semantic metalanguage' (NSM) refers to the theory of language description originated by Anna Wierzbicka and to its principal method of semantic representation, namely, a minilanguage of empirically established universal semantic primes along with their inherent universal grammar. Semantic primes are simple indefinable meanings that surface as identifiable word meanings in all languages. The NSM system has been developed and refined over 30 years, primarily in Australia. There is a large body of descriptive-analytical work in the framework, dealing with lexical, grammatical, and illocutionary semantics across many languages. Although it is controversial, the NSM system is one of the most refined, productive, and comprehensive systems of semantic analysis.

The NSM program has unfolded in four phases. The 1970s to mid-1980s saw the early development of the semantic primitives approach, led by Anna Wierzbicka. The initial inventory of primes was austere (14 in number), their syntax was not well-specified, and explications often involved extremely complex configurations. From the mid-1980s to late 1990s, the search for lexical universals, with its concomitant attention to an ever-widening range of languages, was added to the program. During this period, the number of proposed primes rose to the mid-30s in number. The additional primes enabled a cleaner and more transparent metalanguage. From the mid-1990s onward, the emphasis shifted to the grammar of semantic primes and to thinking of the 'whole metalanguage' as an operational tool. The number of proposed primes stabilized in the mid-sixties. The approach began to experience a notable upswing. From the early 2000s onward, systematization and formalization of the metalanguage began in earnest. No doubt due to the importance of meaning-based studies, the NSM system has attracted considerable attention from adjacent disciplines, especially anthropology and cultural psychology.

The NSM system is arguably approaching the standard expectations of a formalized metalanguage for natural language, in that it aims to combine the explicitness of statements with clarity of expression and its terms and processes are all well-specified and strictly adhered to. On the other hand, because the NSM metalanguage works within such strict confines, it is not a fully natural system. It is an artificial or semi-artificial system based on natural language and understandable on the basis of natural language. It aims to unify formalism and naturalism in a single descriptive and analytical system for meaning in natural language.

Semantic Primes

The foundational assumption of the NSM system is that of the metasemantic adequacy of natural languages: that it is possible to carry out exhaustive reductive paraphrase of the words and grammatical constructions of any language using a subset of the word meanings and grammatical constructions of the language itself. The attractions of this approach can be itemized as follows. First, any system of representation has to be interpreted in terms of some previously known system, and, because the only such system shared by all language users is natural language itself, it makes sense to keep the system of semantic representation as close as possible to natural language. Second, clear and accessible semantic representations enhance the predictiveness and testability of hypotheses. Most other systems of semantic analysis are hampered by the obscurity and artificiality of the terms of description. Third, the system is intended to represent the cognitive reality of ordinary language users, so it would be problematical to employ symbols whose meanings are completely opaque to language users themselves.

The current NSM model is the result of a 30-year program inaugurated by Anna Wierzbicka in her 1972 book *Semantic primitives*. It started with lexical semantics, but has since extended into grammatical and illocutionary semantics and (with the theory of cultural scripts) into cultural pragmatics. A significant body of crosslinguistic evidence indicates that the primes and their associated grammar are universally manifested in all human languages. The current inventory of primes is listed (using English exponents) in Table 1. Each has a well-specified set of syntactic properties (combinatorics, valency, and complementation), so that the system as a whole can be seen as a kind of minilanguage. All these terms identify simple and intuitively intelligible meanings that are grounded in ordinary linguistic experience. The NSM system aims to be exhaustive, that is, capable of adequately paraphrasing the entirety of the vocabulary of any language. The claim is both that semantic primes are essential for explicating the meanings of other words and grammatical constructions and that they cannot themselves be explicated in a noncircular fashion.

Table 1 Table of semantic primes

Substantives	I, YOU, SOMEONE/PERSON, SOMETHING/THING, PEOPLE, BODY
Relational substantives	KIND, PART
Determiners	THIS, THE SAME, OTHER/ELSE
Quantifiers	ONE, TWO, SOME, ALL, MUCH/MANY
Evaluators	GOOD, BAD
Descriptors	BIG, SMALL
Mental/experiental predicates	THINK, KNOW, WANT, FEEL, SEE, HEAR
Speech	SAY, WORDS, TRUE
Actions, events, movement	DO, HAPPEN, MOVE
Existence and possession	THERE IS/EXIST, HAVE
Life and death	LIVE, DIE
Time	WHEN/TIME, NOW, BEFORE, AFTER, A LONG TIME, A SHORT TIME, FOR SOME TIME, MOMENT
Space	WHERE/PLACE, HERE, ABOVE, BELOW, FAR, NEAR, SIDE, INSIDE, TOUCH
Logical concepts	NOT, MAYBE, CAN, BECAUSE, IF
Augmentor, intensifier	VERY, MORE
Similarity	LIKE/WAY

After Goddard and Wierzbicka (2002).

The lexical exponents of primes can be formally complex. English SOMEONE and SOMETHING, for example, consist of two morphological elements, and A LONG TIME and FOR SOME TIME are phrasemes. The NSM claim is that these expressions each represents a unitary meaning. Not surprisingly, in many languages their equivalents are morphologically simple. The exponents of semantic primes can also have multiple realizations (allolexes) in a single language. The 'double-barreled' items in Table 1, such as SOMETHING/THING, SOMEONE/PERSON, and WHEN/TIME, indicate meanings that, in English, are expressed by means of different allolexes in different grammatical contexts. *Something* and *thing*, for example, express the same meaning, except that *something* cannot be used in combination with a specifier. Compare the following three sentences:

something happened
the same thing happened again
I don't know when this thing happened

Similarly, *else* is an English allolex of OTHER, and *don't* is an allolex of NOT. Patterns of allolexy can vary from language to language.

Semantic primes exist, not at the level of whole lexemes, but as the meanings of lexical units (*see* **Polysemy and Homonymy**). Language-specific polysemy can therefore obscure the identification of individual primes. Detailed language-internal evidence is always necessary to support an identification that depends on a polysemy analysis. A great deal of empirical research exists in the NSM literature on the typological semantics of semantic primes. In particular, 'whole metalanguage' studies have been carried out for English, Polish, Malay, Lao, Mandarin, Mbula, Spanish, Korean, and East Cree (Northern East Cree), and more selective studies on French, Italian, Amharic, Japanese, Ewe (Éwé), Yankunytjatjara, and Hawai'i Creole English. On the basis of these studies, semantic primes appear to be lexical universals, in the sense of having an exact translation in every human language (although the term 'lexical' is used here in a broad sense because it includes phrasemes and bound morphemes as well as words proper).

Although it is not possible here to explain how the primes were identified in the first place, an example may be helpful. Consider the word *say*, in sentences such as *Mary said something to me*. How could we paraphrase the meaning of *say* in these contexts using simpler words? An expression such as *verbally express* will not do because terms such as *verbally* and *express* are more complex and difficult to understand than *say* is in the first place. The only plausible line of explication might something like 'Mary did something, because she wanted me to know something'; but this fails because there are many actions a person could undertake because of wanting someone to know something, aside from saying. On the other hand, if we take a word such as *ask*, as in *Mary asked me something*, it seems readily paraphrasable in simpler terms, including SAY, WANT, and KNOW: 'Mary said something to me, because she wanted to know something; she wanted me to say something because of this.' On account of its resistance to paraphrase, SAY is a good candidate for the status of semantic prime. Furthermore, SAY is clearly required for the explication of many other lexical items involving speaking and communication, especially speech-act verbs and many discourse particles, and, in some languages, specialized grammatical constructions too. Upon checking a range of languages, we find that all languages appear to have a word with the same

Table 2 Some common polysemies involving exponents of semantic primes

Prime	*With meanings*	*Languages*
SAY	'speak' or 'make sounds'	Thai, Mandarin, Kalam, Yankunytjatjara
THINK	'worry,' 'long for,' or 'intend'	Amharic, Mandarin
WANT	'like,' 'love' or 'seek'	Spanish, Ewe, Ulwa[a]
HAPPEN	'arrive' or 'appear'	French, Ewe, Mbula
DO	'make'	Malay, Arrernte, Samoan, Kalam
BEFORE	'first,' 'go ahead,' or 'front'	Lao, Samoan, Kayardild,[b] Ewe
FEEL	'taste,' 'smell,' or 'hold an opinion'	Acehnese,[c] Ewe, French, Mandarin
BECAUSE	'from'	Yankunytjatjara, Arrernte

[a]Sumo Tawahka. [b]Gayardilt. [c]Aceh.
Data from Goddard and Wierzbicka (1994).

meaning as English *say*. For example: Malay *kata*, Yankunytjatjara *wangkanyi*, and Japanese *iu*.

As mentioned, polysemy is frequently a complication when we are trying to identify primes and match them up across languages. Often the range of use of equivalents of the same prime do not coincide because, aside from the identical shared meaning, the words in question also have additional meanings that differ from language to language. Frequent polysemies in which semantic primes are involved are summarized in Table 2.

Grammar of Semantic Primes

The inherent syntactic properties of semantic primes (i.e., their combinatorial, valency, and complementation possibilities) are literally universals of syntax, albeit that they can be realized differently, in terms of word order, morphological marking, and constituent structure, in different languages. The most significant single NSM publication on the metalanguage as a whole, and on its syntax in particular, is the two-volume set of studies *Meaning and universal grammar – theory and empirical findings* (Goddard and Wierzbicka, 2002).

The syntactic properties of primes can be seen as falling into three kinds. The first type is basic combinatorics, for example, the fact that substantive primes such as SOMETHING/THING, SOMEONE/PERSON, and SOMEWHERE/PLACE and relational substantives such as PART and KIND can combine with specifiers to form semantic units: THIS THING, THE SAME PERSON, SOMEWHERE ELSE, ONE PART, MANY KINDS, and so on. The second type is an account of basic and extended valencies; for example, the fact that the prime DO can occur not only in its basic frame SOMEONE DID SOMETHING, but also in extended frames such as SOMEONE DID SOMETHING TO SOMETHING (or TO SOMEONE) and SOMEONE DID SOMETHING TO SOMETHING WITH SOMETHING. Valency options, which are argument-like, are distinguished from adjuncts such as temporal and locational phrases along conventional lines. The third type of syntactic properties concerns the propositional complement possibilities of primes such as KNOW, WANT, and THINK, for example, that KNOW can occur in the frame I KNOW THAT SOMETHING HAPPENED IN THIS PLACE and that WANT can occur in frames like I WANT TO DO SOMETHING and I WANT SOMETHING TO HAPPEN. For other examples of valency frames, see Table 3. Primes vary widely in the number of alternative valency frames and complementation options available to them. Although groups of primes share particular properties and can be regarded as falling into natural classes, it is equally true that virtually every prime has some idiosyncratic properties, giving each prime a distinctive syntactic signature.

Table 3 Valency arrays for three semantic primes

Prime	*Array*
DIE	X DIES
HAPPEN	something HAPPENS
	something HAPPENS to X [undergoer]
	something HAPPENS in this place/here [locus]
SAY	X SAYS something
	X SAYS something to someone [addressee]
	X SAYS something about something [locutionary topic]
	X SAYS: ''———'' [direct speech]
	X SAYS something in some words [verbal means]
	X SAYS some words (these words) [cognate object]

Typological research within the NSM framework indicates that the full set of semantic primes is necessary to capture (in maximally clear and translatable terms) the semantic content of language-specific grammatical categories and constructions in the world's languages. (See Table 4 for summary details.) This finding runs counter to the claim advanced by some authors that only a subset of the conceptual primes implied in the lexicon is needed for grammatical purposes.

Using Natural Semantic Metalanguage for Lexical Semantics (Explications)

Explication in terms of semantic primes allows the study of meaning to become concrete and tangible,

Table 4 Some morphosyntactic construction types and associated semantic primes

Primes	*Morphosyntactic constructions*
ONE, TWO, SOME, MUCH/MANY	Number-marking systems (including duals, paucals)
THE SAME, OTHER	Switch-reference, obviation, reflexives, reciprocals
WANT	Imperatives, purposives, uncontrolled marking
KNOW, SEE, HEAR, SAY	Evidential systems
WORDS	Delocutive verbs
DO, HAPPEN	Active marking, passive voice, inchoatives
FEEL, THINK	Experiencer constructions
GOOD, BAD	Benefactives, adversatives
BIG, SMALL	Diminutives, augmentatives
VERY	Superlatives, expressives
NOW, BEFORE, AFTER, A LONG TIME, A SHORT TIME	Tense systems (including degrees of remoteness)
HERE, ABOVE, BELOW, SIDE, NEAR, FAR	Elaborate locational deixis
PART OF	Inalienable possession

especially in comparison with methods that employ abstract and obscure representional devices. NSM explications can be directly or indirectly substituted in place of the expressions they are intended to represent and so can be submitted to the test of substitution *salvo sensu*. There is a substantial body of descriptive empirical work in the NSM framework on many aspects of lexical semantics (*see* **Lexical Semantics: Overview**), grammatical semantics and illocutionary semantics, cultural pragmatics, and, more recently, into universal grammar. The look and feel of NSM explications can be illustrated with a series of thumbnail examples: first, with words that can be explicated directly in terms of semantic primes and, then, with more complex examples that call for the use of intermediate-level semantic molecules.

Explicating Directly into Semantic Primes

Verbs *kill* and *break* The causative verbs (*see* **Causatives: Semantics**) *kill* and *break* are frequently analyzed in the general linguistic literature as CAUSE TO DIE (or CAUSE TO BECOME NOT ALIVE) and CAUSE TO BECOME BROKEN, respectively. The NSM explications are given next. Aside from the fact the NSM system recognizes BECAUSE (rather than CAUSE) as its basic exponent in the causal domain, it can be seen that the explications give a more articulated and nuanced account of the event structure. In both cases, the explications depict an action by the agent X with an immediate effect on the patient Y and, consequently, the cessation of a prior state that otherwise would have continued. In the case of *kill*, an intermediate event is also involved, namely, something happening inside person Y's body.

(1) person X **killed** person Y =
X did something to Y
because of this, something happened to Y at the same time
because of this, something happened inside Y's body
because of this, afterwards Y was not living anymore

Break is both more complex than *kill* and more polysemous. The explication that follows applies only to one sense of the word, as found in examples such as *to break a stick*, *an egg*, *a lightbulb*, *a vase*, or *a model plane*. There is an aspectual component involved, namely that the immediate effect on thing Y 'happened in one moment,' and a final subjective component indicating that the result (namely, that 'Y was not one thing anymore') can be seen as irrevocable or irreversible.

(2) person X **broke** thing Y =
X did something to Y
because of this, something happened to Y at the same time
it happened in one moment
because of this, afterward Y was not one thing anymore
someone could think about it like this: 'it can't be one thing anymore'

It is an interesting fact, and one consistent with the somewhat schematic nature of this explication, that many languages lack any comparably broad term that subsumes many different manners of *breaking*.

Adjectives *sad* and *unhappy* According to NSM research, the meanings of emotion terms involve feelings linked with a characteristic or prototypical cognitive scenario (*see* **Prototype Semantics**) involving thoughts and wants. The scenario serves as a kind of 'reference situation' by which the nature of the associated feeling can be identified. For example, *joy* is a good feeling linked with the thought 'something very good is happening now'; *remorse* is a bad feeling linked prototypically with the thought 'I did something bad.' A large body of emotion explications is presented in Wierzbicka's (1999) *Emotions across languages and cultures*. Consider the explication for English *sad*.

(3) X was **sad**
X felt something because X thought something
sometimes a person thinks like this:
'I know that something bad happened
I don't want things like this to happen
I can't think like this: I will do something because of it now
I know that I can't do anything'
when this person thinks like this, this person feels something bad
X feels something like this

The prototypical scenario involves an awareness that 'something bad happened' (not necessarily to me) and an acceptance of the fact that one cannot do anything about it. This is compatible with the wide range of use of *sad* – for example, that I may feel *sad* when I hear that my friend's dog died or when I think about some unpleasant bickering in my workplace.

This format of explication enables subtle meaning differences to be modeled both across languages and within a single language. Consider some of the ways in which *unhappiness* differs from *sadness*.

1. *Unhappiness* requires the experiencer to have certain real thoughts (although we can say *I feel sad, I don't know why*, it would be a little odd to say *I feel unhappy, I don't know why*).
2. *Unhappy* implies a more intense feeling and a stronger negative evaluation, as implied by the fact that it is less readily combinable with minimizing qualifiers like *a little* or *slightly*.
3. *Unhappy* has a more personal character; we can easily be saddened by bad things that have happened to other people, but we are more likely to be *unhappy* on account of bad things that concern us personally.
4. *Unhappy* does not suggest a resigned state of mind but rather focuses on some thwarted desires. The attitude is not exactly active because we do not necessarily want anything to happen, but it is not passive either.
5. *Unhappy* suggests a state extended in time.

All these differences are modeled in the differences between the two explications.

(4) X was **unhappy**
X felt something because X thought something
sometimes a person thinks like this for some time:
'some very bad things happened to me
I wanted things like this not to happen to me
I can't not think about it'
when this person thinks like this, this person feels something bad for some time
X felt something like this because X thought like this

The Noun *friend* The NSM literature contains many fascinating studies of the meanings of culture-rich words from various languages. Often they can give us a new insight into an entire cultural point of view – across time as well as across space. For example, we can trace changing ideas about personal relationships by tracking the changing uses and meanings of the English word *friend*. Several hundred years ago, *friend* designated an exceptional, intimate, and lifelong bond, but the meaning has since weakened considerably, presumably as social relationships have become more flexible and broadly based. The modern English word *friend* can be explicated as follows:

(5) (my) **friend** =
I think about this person like this:
I know this person well
when I do things with this person, I feel something good
when I am with this person, I feel something good
I know that this person thinks the same about me

With a meaning like this, it makes sense that we can quickly make *new friends* and that there is nothing unusual about a person having *many friends*. In the modern sense, *friends* are people who we know, like, and enjoy doing things with. Several hundred years ago, however, *friend* designated a relationship bound by something closer to *love* than to liking. Samuel Johnson, in his 1755 *Dictionary of the English language*, offered the following definition: "*friend* – one joined to another in mutual benevolence and intimacy." Jane Austen regularly used *friends* to include family members. In this older use, the meaning of *friend* involved knowing someone not just 'well' but 'very well'; and moreover, there were additional components that are missing from the contemporary sense: 'I want this person to know how I feel; I want this person to know what I think about things; I want to do good things for this person.' To get anything like this older meaning in modern English, we have to strengthen the word *friend* with a modifier; to speak of, for example, *a close friend* or *a real friend*. The old meaning lingers on, to some extent, in the word *friendship,* which designates something weightier, more committed, and more long-lasting than merely *being friends*. Many European languages still categorize social relationships rather differently to English. French *ami*, Italian *amico*, German *Freund*, and Polish *przyjaciel* have much in common with *friend* (especially in its older meaning), but there are important differences as well as similarities. Across broader cultural gulfs, the differences are even more substantial.

Explicating Complex Concepts Using Semantic Molecules

According to NSM research some kinds of concept (emotions, values, speech acts, and interpersonal relations) are semantically much simpler than others (artifacts, animals and plants, and many human activities) because the former can be explicated directly in terms of semantic primes, whereas the latter can only be explicated in stages using intermediate-level semantic molecules. For example, the concept that certain kinds of thing are 'made by people' is necessary in the explication of artifact concepts such as *cup, knife,* and *umbrella;* the concept 'animal' is necessary in the explications of *cat*, *dog, horse*, and so on; body-parts concepts are required in verbal meanings such as *eat*, *hit*, and *run*; and almost all concrete vocabulary items require semantic molecules such as 'long,' 'round,' 'flat', and 'hard.'

A semantic molecule is a packet of semantic components that exists as the meaning of a lexical unit – properly speaking, a lexico-semantic molecule. They have a special cognitive significance in that they allow a 'conceptual chunking' that makes it possible to manage concepts of great semantic complexity. The semantic molecule 'make' can be explicated as in (6). It involves a certain intention, some actions involving some materials, and an outcome, that is, something existing which did not exist before. The semantic molecule 'animal' is explicated in (7).

(6) person X **made** something (Y) out of Z (e.g., X **made** an omelette out of eggs)
person X did some things to some things because this person thought like this:
'I want there to be something of kind Y here now
because of this, I have to do some things to these other things (Z)'
because X did like this, after this there was something of kind Y in this place
the other things (Z) were parts of this thing of kind Y

(7) **animals**
a kind of living thing
living things of this kind are like people in some ways, they are not like people in other ways
some parts of their bodies are like parts of people's bodies, other parts of their bodies not like people's bodies
there are many kinds of living things of this kind

In the structure of most complex concepts, there are multiple levels of nesting: molecules within molecules. To see this, it is useful to look at part of the explication for *cats*. The following is the first part of such an explication. Generally speaking, explications for animal terms follow the same general format: (a) category in the taxonomic hierarchy, (b) habitat, (c) size, (d) appearance, (e) behavior, and (f) relation with people. The explication in (8) only includes items (a)–(d). In the case of *cats*, the subsequent sections are very long and elaborate, reflecting the detailed folk knowledge people have of these animals that share their lives. The (a) component establishes *cats* as 'a kind of animal [M].' The notation [M] indicates a semantic molecule. The (b) components claim that *cats* are conceptualized primarily as domestic animals. The size component (c) is defined in relation to the human body, a kind of anthropocentrism that recurs in countless words of diverse types. The components in (d) identify the distinctive physical features of *cats* as soft fur, a round head with pointy ears, a special kind of eyes, whiskers, a long tail, and soft feet with small sharp claws.

(8) **cats** =>
a. a kind of animal [M]
b. they live with people
sometimes they live in places where people live
sometimes they live near places where people live
c. they are not big
a person can pick up [M] one with two hands [M]
d. they have soft [M] fur [M]
they have a round [M] head [M]
their ears [M] stick out [M] on both sides of the top part of the head [M], they are pointed [M]
their eyes [M] are not like people's eyes, they are shiny [M]
they have some stiff [M] hairs [M] near the mouth [M], they stick out [M] on both sides of the mouth [M]
they have a long [M] tail [M]
they have soft [M] feet [M]
they have small sharp [M] claws [M]

Two kinds of semantic molecules predominate in the explication in (8): body-part terms (*hands, head, ears, eyes, mouth, hairs, fur, feet, tail, claws*) and physical descriptors of various kinds (*long, round, pointed, sticking out, soft, stiff, sharp, shiny*). To these two groupings, we can add bodily actions and postures (*eat, climb, jump, fight,* etc.) that are needed in subsequent sections of the *cats* explication; obviously they will require the use of body-part terms as semantic molecules. If we now look into the semantics of body-part terms (*see* **Cognitive Semantics**), it emerges that certain shape descriptors are required as molecules in these explications. For example, *head* (in the sense of a 'human person's head') requires the shape

descriptor 'round [M],' and words such as *arms*, *legs*, and *tail* require 'long [M].'

It would be incorrect to assume that shape descriptors are semantically more basic than all body-part terms, however, because one human body part, namely *hands*, is necessary in the explication of shape descriptors themselves. This is because shape descriptors designate properties that are both visual and tangible, and to spell out the nature of the latter concept requires the semantic prime TOUCH (contact) and the semantic molecule 'hands [M].' For example:

(9) something long e.g., a tail, a stick, a cucumber)
when a person sees this thing this person can
think about it like this:
'two parts of this thing are not like any other parts
because one of these two parts is very far from the other'
if a person's hands [M] touch this thing
everywhere on all sides
this person can think about it in the same way

From an experiential point of view the importance of the semantic molecule 'hands [M]' is perhaps not so surprising. The experience of handling things, of touching them with our hands and moving our hands in an exploratory way plays a crucial role in making sense of the physical world and in our construal of the physical world. It turns out that, unlike many other body-part words, *hands* can be explicated directly in terms of semantic primes, although space prevents us from demonstrating this here. Although shape descriptors such as 'long [M]' are only of a moderate level of semantic complexity, it is interesting that to ordinary intuition they appear so basic and unanalyzable. Presumably this is because they are formed very early in childhood and are subsequently incorporated into the molecular substructure of so many other concepts.

Terms for most natural kinds and artifacts are semantically extremely complex, both because they incorporate numerous semantic molecules and because they encapsulate tremendous amounts of cultural knowledge. For natural kinds, this applies in particular to terms for animal species with which people have close relationships, so to speak, either currently or in historically recent times. English *cat, dog, mouse,* and *horse*, for example, are far richer in conceptual terms than *moose* or *kangaroo*. Similarly, artifact terms can differ in their amount of conceptual information depending on the complexity of the function or functions they are intended to serve, including its degree of cultural embeddedness. For example, a word such as *knife* is simpler than one such as *cup* because *cup* involves a great deal more social information.

Other Uses of Semantic Primes

The metalanguage of semantic primes can be used not only for lexical and grammatical semantics, but also as a notation for writing cultural scripts, that is, hypotheses about culturally shared assumptions, norms, and expectations that help regulate interaction in different cultural settings. By using simple crosstranslatable expressions, this approach to cultural pragmatics (or ethnopragmatics) avoids the implicit terminological ethnocentrism of conventional approaches that rely on complex technical and/or English-specific descriptors. Cultural scripts written in semantic primes aim to present an insider perspective on cultural norms in terms that are accessible to outsiders. The NSM metalanguage can also be used to spell out the meanings conveyed by nonverbal signals, such as facial expressions, gestures, and body postures.

Natural versus Nonnatural Meaning

A Barber, The Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

Grice's Distinction

H. P. Grice noticed a potentially confusing lexical ambiguity in the word 'means' (see Grice, 1957). Contrast claim (1) with claim (2):

(1) The flooded river means that the mountain snow is melting
(2) The sentence 'La neige des montagnes fond' means that the mountain snow is melting

If it turned out that the mountain snow was not melting, then claim (1) would have to be withdrawn, whereas claim (2) would not. The French sentence in (2) would mean what it does even if it was untrue. Grice distinguishes what he calls natural meaning, which is what 'means' means in the context of a claim such as (1), from nonnatural meaning, invoked in (2). He offers a range of criteria for distinguishing the two kinds of meaning – 'meaning$_{N}$' and 'meaning$_{NN}$' as he abbreviates them – but the key difference is sometimes put in terms of meaning$_{N}$, unlike meaning$_{NN}$, being *factive*: what is meant$_{N}$ can only be a fact, whereas what is meant$_{NN}$ need not.

Sentences are not the only kind of entity that may be said to have meaning$_{NN}$. Others include people, as when we say that so-and-so meant something; utterances of a sentence as opposed to the sentence itself; and mental states, such as beliefs, which have representational content without necessarily representing accurately. The distinction seems to be available no matter what one takes to be the primary bearers of meaning$_{NN}$.

Grice stressed this distinction because he was interested in nonnatural meaning, which he deemed to be harder to pin down and so more in need of investigation than natural meaning. Natural meaning is simply a relation of necessitation between one event and

Natural versus Nonnatural Meaning

A Barber, The Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

Grice's Distinction

H. P. Grice noticed a potentially confusing lexical ambiguity in the word 'means' (see Grice, 1957). Contrast claim (1) with claim (2):

(1) The flooded river means that the mountain snow is melting
(2) The sentence 'La neige des montagnes fond' means that the mountain snow is melting

If it turned out that the mountain snow was not melting, then claim (1) would have to be withdrawn, whereas claim (2) would not. The French sentence in (2) would mean what it does even if it was untrue. Grice distinguishes what he calls natural meaning, which is what 'means' means in the context of a claim such as (1), from nonnatural meaning, invoked in (2). He offers a range of criteria for distinguishing the two kinds of meaning – 'meaning$_N$' and 'meaning$_{NN}$' as he abbreviates them – but the key difference is sometimes put in terms of meaning$_N$, unlike meaning$_{NN}$, being *factive*: what is meant$_N$ can only be a fact, whereas what is meant$_{NN}$ need not.

Sentences are not the only kind of entity that may be said to have meaning$_{NN}$. Others include people, as when we say that so-and-so meant something; utterances of a sentence as opposed to the sentence itself; and mental states, such as beliefs, which have representational content without necessarily representing accurately. The distinction seems to be available no matter what one takes to be the primary bearers of meaning$_{NN}$.

Grice stressed this distinction because he was interested in nonnatural meaning, which he deemed to be harder to pin down and so more in need of investigation than natural meaning. Natural meaning is simply a relation of necessitation between one event and

another, for example a causal relation such as the one alleged in (1). The investigation of nonnatural meaning is handicapped, he felt, by confusions that arise through failure to see the distinction between it and meaning$_N$. In his 1957 paper, he criticizes the attempt to understand meaning$_{NN}$ in terms of meaning$_N$, and then appeals to the distinction in the course of blocking objections to his own theory of meaning$_{NN}$.

Grice's Theory of Non-natural Meaning

Grice's distinction is acknowledged even by those who do not endorse his theory of meaning$_{NN}$. But this latter has been influential nonetheless (see Schiffer, 1972 for a development of it, and Schiffer, 1987 for a retraction). The meaning$_{NN}$ of an act, he suggests, turns entirely on the intention of its agent. Not all acts have meaning$_{NN}$, but those that do are performed with a triplex of intentions. First, the agent intends to bring about an effect of some kind in the mind of her audience – a change of belief, for example. Second, she intends to be recognized by this audience as having this first intention. Third, she intends the effect to arise *through* this recognition. If an act is performed with intentions of this form, then the intended effect is said by Grice to be the act's meaning$_{NN}$ (or, equivalently, it is what the agent meant_{NN} by the act; or again, it is what the expression used means$_{NN}$ on that occasion).

In practice, recognition of the intention is usually achievable only because of the close association between acts typed according to whether they share the same meaning$_{NN}$ and acts typed according to an overt, recognizable pattern. In the linguistic case, for example, typing according to the sentence uttered will usually group together utterances with the same meaning$_{NN}$. Shared knowledge of which sentences are paired with which meanings$_{NN}$ is what makes individual acts of meaning$_{NN}$ possible in the first place. This leads Grice to introduce a derivative notion, timeless meaning$_{NN}$, which is the meaning associated with the repeated use of a particular pattern. Sometimes this timeless meaning$_{NN}$ of a sentence is distinct from the meaning$_{NN}$ of an utterance of it on an occasion. Someone could use the sentence *I know where you live* to mean$_{NN}$ something distinct from what it timelessly means$_{NN}$. It is no coincidence that Grice was among the first to notice and develop a theory of the phenomenon of implicature (see Grice, 1975).

Other Remarks

Though the existence of a distinction between natural and nonnatural meaning is clear once pointed out, it is easy to become confused over its precise nature. After all, utterances are events and, as such, have meaning$_N$ as well as meaning$_{NN}$. And (3) is true on both readings of 'means':

(3) The canyon-dweller's shout of "Here comes an echo" meant that we would shortly hear an echo

Moreover, the utterances of an omniscient truth-teller – God, for example – mean$_N$ whatever they mean$_{NN}$. Efforts by philosophers of mind and language in the 1980s to understand systems of representation naturalistically (see Millikan, 1984; Dretske, 1988) may shed light on these cases. A distinction is sometimes drawn between what an instance of mental representation R *indicates* and what it *represents*. What it indicates (or what information it carries) is understood entirely in terms of the causal relations instances of R tend to enter into – something like meaning$_N$. It represents not what it indicates but *what it is the function* of instances of R to indicate, within the representational system as a whole. So when the representation system, i.e. the mind or some part of it, is functioning properly, an instance of R will indicate what it represents. Misrepresentation is a matter of functional breakdown in the system, resulting in instances of R that fail to indicate what they represent, i.e., what it is their function to indicate. An omniscient truth-teller can be thought of as a properly functioning representational system, which is why God's utterances mean$_N$ (or indicate) what they mean$_{NN}$ (or represent).

any claims are analytic, or true just in virtue of their meaning and not in virtue of whether they fit with observation (see also Burge, 1992: 6–9). Statements that seem to be true just in virtue of their meaning, and even Russell's 'laws of logic,' are not in principle immune to disconfirmation any more than ordinary empirical claims, so there is little reason to exclude the latter from one's account of knowledge.

Quine was criticized for straying from his naturalist scruples when it came to language. Based partly on worries about language acquisition, Quine argued in favor of two theses: the indeterminacy of translation (1960) and the inscrutability of reference (1960, 1970). According to the former, there is no fact of the matter about which translation among competing translations of a given language into another is correct. The claim is not that it is rather difficult to be sure one has achieved the proper translation but that there is no fact of the matter about which is correct at all. The latter thesis claims that there is no fact of the matter about what specific terms in a language refer to. Taken together, these theses led Quine to a general skepticism about meaning and reference.

Chomsky (1968, 1975, 1980) objected to Quine's theses on the simple grounds that they contradicted Quine's claims about every other science. Just about everyone has agreed that the empirical evidence underdetermines one's theory of a phenomenon. So, indefinitely many theories can account for any given set of evidence. This does not interfere with science's progress, and it is not clear why the study of language should answer to a higher standard than the other sciences.

> If the underdetermination of physical theory by evidence does not lead us to abandon the 'realistic point of view' [...] then the comparable underdetermination of grammatical theory by evidence does not support Quine's claim that there is no fact of the matter [...] to be right or wrong about .... (Chomsky, 1975: 183)

Complaints in a similar vein can be found in Fodor and Lepore (1992: 70–82). Quine (1960: 75–6, 1968) argued that the cases are not parallel. In a remark that nicely paralleled Quine's quote (1969: 76), Robert Fogelin complained:

> ... Quine's attempt to trace a path from stimulation to science is carried out with almost no concern for the psychological reality of the process, that is, with almost no references to empirical investigations of how language is actually acquired. (1997: 561)

In the end, Quine's controversial claims should, by his own lights, be subject to empirical confirmation or disconfirmation. According to linguists and many philosophers, the weight of the evidence seems to be against him. Scott Soames (2003: 404–405) suggested that Quine's views might not admit of empirical support one way or the other, which would, on Quinean grounds, render them meaningless and useless.

Naturalized philosophy of mind tries to show how facts about intentionality, consciousness, meaning, and the like can be explained in terms of what the natural sciences – particularly psychology, neuroscience, and biology – tell us about ourselves. Here, too, we find problems with normativity. For example, concepts have intentional contents. They are about things and states of affairs. What, then, makes my concept of snow about snow? Perceptual encounters with snow cause me to think of snow and have certain beliefs about it. Perhaps, then, my concept of snow has its content in virtue of what causes me to deploy it. Cleverly placed whipped cream, however, can fool me into believing that there is snow on my windowpane. Whipped cream is not snow, of course, and my snow concept is not about whipped cream at all. It cannot be just anything causing me to deploy my snow concept figures in its content. If it did, the content would be quite disjunctive – snow or whipped cream or cotton gauze at a distance, etc. – and none of my uses of the concept would be mistaken. Any naturalistic theory of content must explain how we incorrectly use concepts, and this appeals to norms regulating their application. Scientific theories tend not to appeal to norms. Attempts to naturalize content are due to Fred Dretske (1981), Ruth Millikan (1984), and Jerry Fodor (1990), among others. Burge (1992) helpfully reviewed the development of naturalized philosophy of mind and language in the 20th century (*see* **Representation in Language and Mind**).

Chomsky's (1980, 1995, 2000) commitment to naturalism has been 'methodological' in that he has taken scientific explanation to be the goal when we investigate language and mind. He famously denied that there is an interesting 'metaphysical' sense to naturalism according to which research aims to explain mental and linguistic phenomena in physical or biological terms. Chomsky has been skeptical of metaphysical naturalism because, first, reduction is rarely a prerequisite for conducting science. For example, biology has not been reduced to physics, but it is a science nonetheless. And second, we do not have a clear enough conception of the physical for the metaphysical project to make sense.

> Lacking a concept of 'matter' or 'body' or 'the physical' we have no coherent way to formulate issues related to the 'mind-body problem' ... the sciences postulate

> whatever finds a place in intelligible explanatory theory, however offensive that may be to common sense. (Chomsky, 1995: 4–5)

Naturalists are committed to following science wherever it leads, but we do not understand the world well enough to make a stronger, metaphysical commitment to reducing the mind to the physical. Since our notion of what is physical is frequently in flux, it seems odd to insist that the mind must be explicable in terms of it. Responses to Chomsky's views, with replies by Chomsky, can be found in Antony and Hornstein (2003).

Biology, more than most other sciences, must deal with normative notions. What is the function of this trait? Is it adaptive? What was its original purpose? And so on. Philosophers have not missed the fact that biology offers a promising approach to the moderate naturalists' goals. Alex Rosenberg (1996: 4) suggested that "[i]f naturalism is to replace *a priori* first philosophy with scientific theory, then at least for the present the theory in question will be Darwin's." Millikan's work (1984, 1993) has focused on explicating a naturalistically acceptable notion of biological function and applying it to problems in the philosophy of mind and language. Dretske (1988), David Papineau (1993), Karen Neander (1995), and Daniel Dennett (1995), among others, have followed her lead.

Nauru: Language Situation

B Palmer, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

The world's smallest independent republic, Nauru is a single island, an uplifted coral reef with a total land area of 21 square kilometers, located just south of the equator in Micronesia, northeast of New Guinea in the central-western Pacific.

Nauru was initially settled over 2000 years ago by Austronesian speakers. It remained isolated from Western influence until the arrival of whalers during the 19th century. Annexed by Germany in 1888, Nauru was taken over by Australia in 1914 and administered as a trusteeship until independence in 1968. Phosphate was discovered there in 1896, and throughout the 20th century, Nauru was extensively mined, leaving the island's large central plateau as barren as a lunar landscape. The current population of Nauru predominantly lives on the narrow coastal perimeter.

The country is home to one indigenous language, Nauruan (*Ekakairũ Naoero*). Nauruan belongs to the Micronesian branch of Oceanic within the Austronesian language family. Nauruan on its own forms a first-order subgroup of Micronesian, as a sister of the Nuclear Micronesian grouping comprising all the remaining members of the Micronesian branch (including Kiribati, Marshallese, Kosrean, etc). This suggests that Nauruan split away from Proto-Micronesian very early, probably representing the first wave of migration away from the Proto-Micronesian homeland, which may have been Kosrae or Kiribati. At the time of European contact, several distinct dialects of Nauruan were spoken, but these distinctions have now effectively disappeared.

Despite its status as the sole indigenous language, Nauruan is the first language of only about 50% of the country's population of approximately 13 000 inhabitants. The remaining population, largely workers associated with the phosphate mines, includes a sizeable Kiribati-speaking community of about 1700 and smaller language communities of other Pacific Islanders, including Fijians, Marshallese, Kosreans, and Tuvaluans. These communities total close to 1000 individuals, some of whom speak Nauruan as a second language. In addition, Nauru is home to about 600 non-Nauruan native English speakers and about 600 Chinese speakers of Cantonese, many of whom apparently also speak Chinese Pidgin English.

Government policy is to support Nauruan, and a language board has been established. The board is currently preparing a dictionary using two orthographies, pending a decision about which to use. However, although Nauruan has semiofficial status as the national language, a policy of bilingualism with English exists. Both English and Nauruan are official languages, and English predominates in official government business and in commerce. Education is bilingual in Nauruan and English. Almost all native Nauruan speakers are bilingual in English, and children are reportedly no longer learning Nauruan as their first language. The language's future is far from secure.

Navajo

H Landar

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, p. 2764, © 1994, Elsevier Ltd.

Navajo is an Athapaskan (Apachean) language, with perhaps 200 000 speakers in Arizona, New Mexico, and Utah. Vowels /i e o a/ are single, clustered, nasalized (ą), and of low or high pitch. Syllables have strong, medium, or ordinary stress. Junctures are rising, falling, and sustained. Voiceless stops are labial, apical, and velar /p t k/ written *b*, *d*, *g*; labial and palatal sonorants are /w y/; voiceless nonlabial stops /t k/ and affricate clusters with /t/ have aspirated counterparts, e.g., /th kh/ written *t*, *k*, /tsh tšh/ written *c*, *č*. Aspirated segments are allophones of /h/; checked segments, of /ʔ/. Thus /tšʔ/ is the componential reduction of *č*. Voiceless nonfaucal fricatives have voiced homorganic counterparts, apical /s z/, palatal /š ž/, velar /x ɣ/, lateral /ł l/. Nasals are /m n/. Navajo

The world's smallest independent republic, Nauru is a single island, an uplifted coral reef with a total land area of 21 square kilometers, located just south of the equator in Micronesia, northeast of New Guinea in the central-western Pacific.

Nauru was initially settled over 2000 years ago by Austronesian speakers. It remained isolated from Western influence until the arrival of whalers during the 19th century. Annexed by Germany in 1888, Nauru was taken over by Australia in 1914 and administered as a trusteeship until independence in 1968. Phosphate was discovered there in 1896, and throughout the 20th century, Nauru was extensively mined, leaving the island's large central plateau as barren as a lunar landscape. The current population of Nauru predominantly lives on the narrow coastal perimeter.

The country is home to one indigenous language, Nauruan (*Ekakairũ Naoero*). Nauruan belongs to the Micronesian branch of Oceanic within the Austronesian language family. Nauruan on its own forms a first-order subgroup of Micronesian, as a sister of the Nuclear Micronesian grouping comprising all the remaining members of the Micronesian branch (including Kiribati, Marshallese, Kosrean, etc). This suggests that Nauruan split away from Proto-Micronesian very early, probably representing the first wave of migration away from the Proto-Micronesian homeland, which may have been Kosrae or Kiribati. At the time of European contact, several distinct dialects of Nauruan were spoken, but these distinctions have now effectively disappeared.

Despite its status as the sole indigenous language, Nauruan is the first language of only about 50% of the country's population of approximately 13 000 inhabitants. The remaining population, largely workers associated with the phosphate mines, includes a sizeable Kiribati-speaking community of about 1700 and smaller language communities of other Pacific Islanders, including Fijians, Marshallese, Kosreans, and Tuvaluans. These communities total close to 1000 individuals, some of whom speak Nauruan as a second language. In addition, Nauru is home to about 600 non-Nauruan native English speakers and about 600 Chinese speakers of Cantonese, many of whom apparently also speak Chinese Pidgin English.

Government policy is to support Nauruan, and a language board has been established. The board is currently preparing a dictionary using two orthographies, pending a decision about which to use. However, although Nauruan has semiofficial status as the national language, a policy of bilingualism with English exists. Both English and Nauruan are official languages, and English predominates in official government business and in commerce. Education is bilingual in Nauruan and English. Almost all native Nauruan speakers are bilingual in English, and children are reportedly no longer learning Nauruan as their first language. The language's future is far from secure.

This article is reproduced from the previous edition, volume 5, p. 2764, © 1994, Elsevier Ltd.

Navajo is an Athapaskan (Apachean) language, with perhaps 200 000 speakers in Arizona, New Mexico, and Utah. Vowels /i e o a/ are single, clustered, nasalized (ą), and of low or high pitch. Syllables have strong, medium, or ordinary stress. Junctures are rising, falling, and sustained. Voiceless stops are labial, apical, and velar /p t k/ written *b*, *d*, *g*; labial and palatal sonorants are /w y/; voiceless nonlabial stops /t k/ and affricate clusters with /t/ have aspirated counterparts, e.g., /th kh/ written *t*, *k*, /tsh tšh/ written *c*, *č*. Aspirated segments are allophones of /h/; checked segments, of /ʔ/. Thus /tšʔ/ is the componential reduction of *č*. Voiceless nonfaucal fricatives have voiced homorganic counterparts, apical /s z/, palatal /š ž/, velar /x ɣ/, lateral /ł l/. Nasals are /m n/. Navajo

lacks a Proto–Athapaskan series of labialized consonants and contrast of front and back velar consonants.

Navajo is a SOV language. Word classes are nouns, postpositions (adjuncts), verbs, and particles. Their functions define syntactic classes, nominals, adjunctives, verbals, and relationals. Pronominal prefixes of nouns and postpositions are similar in form but not in meaning; those of nouns are possessive, whereas those of postpositions translate as datives and accusatives, with adverbial stems. Compare *ší* 'I' (independent subject pronoun), *ši-má* 'my mother' (noun), *ši-tšʔɩ̨ʔ* 'me-towards' (postposition); *ni* 'you (SG),' *ni-lɩ̨ʔ* 'your horse(s),' *nitšʔɩ̨ʔ* 'toward you'; *bí* 'he (she, it, they),' *b-ádí* 'his older sister(s),' *b-aa* 'to him.'

Verb prefixes take 10 positions before a stem: adverbial, iterative, plural, objective, deictic, aspectual, modal, perfective, subjective, and classifier. Stem shapes vary for modes (imperfective, perfective, optative, and others) and aspects (momentaneous, continuative, and others); some stems, however, are invariable. Neuter verbs are intransitive; active verbs include agent and patient; third persons and other prefixes may have a zero (∅) form. Thus *ní-ʔaah* 'you (SG) move it (as a compact or round object)'; cf. *š-aa ní-ʔaah* 'give it to me'; that is, 'to me you move it as a compact object.' The stem *-ʔaah* belongs to a classificatory gender system for movement or handling of various objects (e.g., a container with contents, a living being, a flat flexible object, a thin rigid object, a ropelike object, and others). Navajo shares verbal patterns with other Athapaskan languages but has lost a rich Proto–Athapaskan system of prefixation and suffixation for aspect and mode.

Sentences are transformed principally by rules for moving words or inserting enclitics (a subclass of particles). The enclitic *íš* 'is it?' makes one type of question: *ʔaškii* ('boy') *ʔatʔééd* ('girl') *yiztsǫs* ('he kissed her') *íš* ('is it?'), 'did the boy kiss the girl?' Negatives are generated commonly by *doo … da*: *doo yiztsǫs da* 'he did not kiss her.' The prefix *yi-* alternates with *bi-* to indicate the third person object when the subject is a third person (∅ in position (i)). *Yi-* and *bi-* involve a hierarchy of animacy for some speakers; they may preserve the Proto–Athapaskan–Eyak semitransitive category identified by Krauss (1965). Often *yi-* shows that an action is controlled or semitransitive while *bi-* shows full transitivity on a foregrounded object. Thus object advancement from *ʔaškii ʔatʔééd yiztsǫs* 'the boy kissed the girl' to *ʔatʔééd ʔaškii biztsǫs* 'the girl was kissed by the boy' foregrounds NP_2 and cancels semitransitivity.

Tomás Navarro Tomás, born in La Roda (Albacete), was Spain's leading specialist in phonetics and dialect geography. His long and productive career was divided between Spain and, after the Spanish Civil War, Columbia University.

His first linguistics publications studied Old Aragonese verbal morphology. In 1911, Navarro Tomás was appointed by his teacher Ramón Menéndez Pidal to direct the Phonetics Laboratory attached to the newly created Centro de Estudios Históricos. Thereafter, the bulk of his efforts were devoted to a scholarly and scientific objective description of the facts of Spanish pronunciation. In the second decade of the 20th century, he published a series of detailed phonetic studies on Spanish pronunciation (all in the *Revista de Filología Española*), which paved the way for the first edition (1918) of his most successful and influential book, *Manual de pronunciación española*, a work that was revised, expanded, and oft-reprinted. Navarro Tomás was elected a member of the Royal Spanish Academy of the Language in 1935. His inaugural lecture *El acento castellano* (1935) led to further work on Spanish intonation (Navarro Tomás, 1946).

Though he continued to publish on Spanish phonetics and phonology (from a Praguean structuralist perspective), Navarro Tomás turned to dialect geography, viewed principally as the distribution of phonetic variation. He became Director of the *Atlas lingüístico de la Península Ibérica*. The fieldwork begun in 1931 was interrupted by the Spanish Civil War in 1936 and continued later in the 1940s and 1950s. In 1962, he published the first volume (with

Nebrija, Antonio de (1444?–1522)

G Haßler, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

Antonio Martínez de Cala y Xavara, known under his pseudonym Elio Antonio de Lebrija, was born in Lebrija (Spain) in 1444 and died in Alcalá de Henares on July 2, 1522. His name has several orthographic variations: apart from Antonio de Lebrija, in the *Introductiones Latinae* of 1501 it is spelled as Antonius Nebrissen, and in the *Introductiones Latinae* of 1481, Antonius Lebrixen. He was an important Spanish humanist and the author of the first grammar of a Romance language.

The great humanist was born in ancient Nebrissa, which is called Lebrija nowadays, in the province of Sevilla and not far away from the province of Cádiz. His father was Juan Martínez de Cala and his mother, Catalina de Xarana y Ojo. He was the second of five children. The young Nebrija studied philosophy and mathematics in Salamanca. At the age of 19, he left for Italy in order to continue his studies in theology, jurisprudence, and classical languages for 10 years at the Collegio di San Clemente of Bologna as well as in Rome, Florence, Pisa, and Padua. When he returned to Spain, he worked for the archbishop Fonseca in Seville. After three years as a private tutor he held various chairs at the University of Salamanca (1476–1487), teaching mainly grammar and rhetoric. He resigned from the university and spent the following years in the house of his former student, the future cardinal and archbishop of Seville, Juan de Zúñiga. He wrote most of his works during this time. Then he contributed to the project of a polyglot Bible under the direction of Cisneros. In 1503 he gave up this collaboration for another chair at the University of Salamanca, this time teaching jurisprudence and theology. After having lost this post in 1509 and working as a chronicler of the court for a short time, he accepted the chair of rhetoric at Salamanca in the same year. In 1513 he left Salamanca for good and withdrew to Alcalá de Henares. He was appointed to the chair of rhetoric of the Universidad Complutense de Alcalá de Henares, which he was to hold until his death, and the cardinal Cisneros commissioned him to work on the Biblia Poliglota Complutense.

Nebrija wrote on various domains of cosmography, botanics, and theology. He is known for his efforts to

The great humanist was born in ancient Nebrissa, which is called Lebrija nowadays, in the province of Sevilla and not far away from the province of Cádiz. His father was Juan Martínez de Cala and his mother, Catalina de Xarana y Ojo. He was the second of five children. The young Nebrija studied philosophy and mathematics in Salamanca. At the age of 19, he left for Italy in order to continue his studies in theology, jurisprudence, and classical languages for 10 years at the Collegio di San Clemente of Bologna as well as in Rome, Florence, Pisa, and Padua. When he returned to Spain, he worked for the archbishop Fonseca in Seville. After three years as a private tutor he held various chairs at the University of Salamanca (1476–1487), teaching mainly grammar and rhetoric. He resigned from the university and spent the following years in the house of his former student, the future cardinal and archbishop of Seville, Juan de Zúñiga. He wrote most of his works during this time. Then he contributed to the project of a polyglot Bible under the direction of Cisneros. In 1503 he gave up this collaboration for another chair at the University of Salamanca, this time teaching jurisprudence and theology. After having lost this post in 1509 and working as a chronicler of the court for a short time, he accepted the chair of rhetoric at Salamanca in the same year. In 1513 he left Salamanca for good and withdrew to Alcalá de Henares. He was appointed to the chair of rhetoric of the Universidad Complutense de Alcalá de Henares, which he was to hold until his death, and the cardinal Cisneros commissioned him to work on the Biblia Poliglota Complutense.

Nebrija wrote on various domains of cosmography, botanics, and theology. He is known for his efforts to

reform the instruction of Latin. In 1481 he published his *Introductiones Latinae*. Joining philology with pedagogy and illustrating rules with literary data, he tried to overcome the old and complicated method of teaching and learning Latin. His main sources were Donatus, Priscan, and Charisius, as well as the *grammatici iuniores*, and especially Lorenzo Valla's *Elegantiae linguae Latinae*. He adopted three principles of this work: empiricism, not speculation; construction, not causes; authors, not grammars.

Encouraged by the success of the book, he published his famous *Gramática castellana* in 1492. It was the first grammar written in Europe on a vernacular language, and it is subdivided traditionally into orthography, prosody, etymology, and syntax. He wrote it for ideological reasons: the language must follow the political improvement of a people, which he proved by examples from antiquity and tried to apply to the condition of the Spanish after the victory over the Moorish inhabitants of the south of Spain. But the main reason for writing his grammar was the teaching of Latin: children should first be taught the grammar of their mother tongue before they learn Latin. Nebrija dedicated his grammar to the Catholic Queen Isabel I, claiming that Spain reached its political unity and was about to conquer the world. In this situation language and political power had to be closely linked. By codifying the Spanish language Nebrija wanted to raise it to the ranks of classical languages and protect it from further changes. Nebrija's grammar is evidence of linguistic consciousness in Spain at the beginning of the Siglo de Oro, and it is the first systematic exposition of the Spanish language. In 1517 he published the rules of Spanish orthography (*Reglas de ortografía española*). Nebrija asserted the need for a one-to-one relationship between pronunciation and spelling.

Nebrija is also the author of a Latin–Spanish *Lexicon* (1492) and a Spanish–Latin *Vocabulario* (1495). These dictionaries were as successful as the *Introductiones Latinae* and were republished many times. The Spanish grammar, however, was not a success and was not published again until the 18th century.

Negation

P Ramat, University of Pavia, Pavia, Italy

© 2006 Elsevier Ltd. All rights reserved.

Negation in natural languages is very different from and much more complicated than negation in logic or mathematics. In many languages, for instance, it is not true that two negations correspond to a positive value according to the well-known formula $\neg\neg P = P$. Even in Latin, in which *non nullus* (lit. 'not nobody') means – according to classical texts – 'somebody,' we may find two negative terms preserving a negative value. Compare, for example, *iura te non nociturum esse homini … nemini* (Plautus) 'swear that you will not harm anybody' with Cockney and substandard English *I don't see nothin' nowhere* (for a not perfect correspondence between logical and linguistic negation, see later section, 'Negation and Presuppositions').

Consider first a declarative negation that refers to a real state of affairs. This declarative negation has to be distinguished from a prohibitive (e.g., *Do not*

reform the instruction of Latin. In 1481 he published his *Introductiones Latinae*. Negation in natural languages is very different from and much more complicated than negation in logic or mathematics. In many languages, for instance, it is not true that two negations correspond to a positive value according to the well-known formula $\neg\neg P = P$. Even in Latin, in which *non nullus* (lit. 'not nobody') means – according to classical texts – 'somebody,' we may find two negative terms preserving a negative value. Compare, for example, *iura te non nociturum esse homini … nemini* (Plautus) 'swear that you will not harm anybody' with Cockney and substandard English *I don't see nothin' nowhere* (for a not perfect correspondence between logical and linguistic negation, see later section, 'Negation and Presuppositions').

Consider first a declarative negation that refers to a real state of affairs. This declarative negation has to be distinguished from a prohibitive (e.g., *Do not*

lean out), which does not refer to a real state of affairs and, on the contrary, is used in order to prevent the realization of a state of affairs (see later section, 'Prohibitive NEG'). The linguistic operation of negation (NEG) consists in denying the truth value of the negated sentence, or of a part of the sentence. By applying a NEG operator (π_{NEG}) to sentences such as those in Examples (1a) and (1b),

(1a) John likes to work.
(1b) John likes beer at lunch.

we get

(1a′) John does not like to work.
[it is not true that [John likes to work]]
(1b′) John does not like beer at lunch.
[John does like beer, [$\pi_{\text{NEG ADV SATELLITE}}$ at lunch]]

Negative sentences are most frequently used to correct states of affairs assumed by the speaker to be either shared knowledge or to represent the commonest ones to be expected in the contextual situation. *The post hasn't been delivered this morning* is a felicitous message only under the assumption, shared by speaker and hearer, that the post has to be delivered every day. This is the reason why negative sentences are normally not used to introduce new propositions or new referents. The sentence *A train didn't arrive yesterday*, extrapolated from a situational context that makes a sense possible, is deemed to be rather odd; not so its affirmative counterpart, *A train arrived yesterday*. Consider also *When didn't a/the train arrive?*: it does not make sense to ask when an event did not happen.

The content resulting from a negated sentence can be either negative or positive: *I know* → *I do not know*, and *I ignore* → *I do not ignore*. There are no known languages that do not possess a means for negating the truth value of a positive sentence. NEG is a linguistic universal: for cognitive and pragmatic reasons, every language must have the possibility of asserting that the state of affairs expressed by a sentence is not true.

The 'Scope' of the NEG. Sentence vs. Phrase Negation

By adducing Examples (1a) and (1b), the notion of 'scope' has already been introduced implicitly. The widest scope of NEG (i.e., its sphere or domain of operation) is the sentence (S), but NEG may apply also to sentence subunits, that is to syntagms (noun phrases (NP), adverbs (ADV), prepositional phrases) or even to lexemes:

(2) $_{\text{S[NP}}$[Many arrows] hit the target] →
$_{\text{S[}\pi\text{NEG NP}}$[Not many arrows] hit the target]

(3) $_{\text{S}}$[Many stars are $_{\text{PRED}}$[visible]] → $_{\text{S}}$[Many stars are $_{\text{[}\pi\text{NEG NP PRED}}$[invisible]]

(4) $_{\text{S[ADV}}$[Consciously,] Mary smiled] →
$_{\text{S[}\pi\text{NEG ADV}}$[Unconsciously,] Mary smiled]

Examples (2)–(4) are affirmative sentences (a negative counterpart of Example (2) would be *Many arrows didn't hit the target*).

It may be concluded that the phrase/lexeme negation operates by applying a π_{NEG} to the phrase/lexeme to be negated, i.e., by negating the truth condition or the existence of that phrase/lexeme. However, in Example (5),

(5) Mary doesn't drive dangerously/like a stunt car driver.

NEG has in its scope just the modal and the sentence makes sense only if the presupposition is that Mary is capable of driving. Only when NEG applies to S and its predicative (PRED) nexus do we get a negative sentence. Consider the English sentence in Example (6):

(6) You may not read the newspaper today.

This has two different intonations (suprasegmental traits), which correspond to two different readings: *You are not allowed to read the newspaper today* and *You have the option of not reading the newspaper today*. Only by the first reading do we have a negative sentence, and, in fact, the scope of NEG includes in this case the entire predication. This is not the case with the second reading. Now, this is precisely the reason why negative quantifiers (the so-called negative pronouns) make a sentence negative. Consider Example (7a):

(7a) Nobody knows my sorrow.

In other words, *There is no x such that x knows my sorrow* – the entire predication lies in the scope of 'nobody.' Note that this holds true also for negative quantifiers in object position:

(7b) John had nothing, he knew nobody.

Not every language possesses this kind of quantifier. Compare Example (8a), Danish,

(8a) Har du set noget? – Nej, jeg
Have you seen something? No I
–
har ikke set noget.
have not seen something.
'Have you seen anything? – No, nothing.'

with Example (8b):

(8b) Har du ikke set noget? – Jo,
Have you not seen something – Yes
jeg har set noget.
I have seen something.
'Haven't you seen anything? – Yes, I have seen something.'

The opposition between 'nothing' and 'something/anything' is realized syntactically in the context and not lexically, and *noget* acquires a negative meaning if it is in the scope of NEG (*ikke*), as in the answer of Example (8a) and in the question of Example(8b).

Negation and Presuppositions

Commenting on Example (5), reference has been made to the presuppositions that make a sentence felicitous or not (in Grice's sense). As may be argued from the 'tag question' *didn't they?* at the end of Example (9)

(9) They almost sold it, didn't they?

the sentence is felt to be positive, even though the proposition it asserts entails the negative state of affairs that they did not sell it (see Taglicht, 1984: 108). Conversely, Example (5) does not imply that Mary does not drive, but, quite on the contrary, that she drives (cf. also Example (1b)). What determines the negative effect of π_{NEG} and its applications are the pragmatic presuppositions at the discourse and situation level.

Typology of Negation

The means for realizing π_{NEG} show a large cross-linguistic variety, as may easily be seen by comparing the simple declarative negative English sentence in Example (10a) with its translations in various languages (Examples (10b)–(10k)):

(10a) John doesn't eat fish.
(10b) French: Jean ne mange pas de poisson.
J. NEG eats NEG PART fish
(vs. Jean mange du$_{PART+ART}$ poisson)
(10c) German: Hans ißt keinen Fisch.
J. eats no:ADJ fish
(vs. Hans ißt Fisch 'J. eats fish')
(10d) Finnish: Jukka ei syö kalaa.
J. NEG-3SG eat fish
(vs. Jukka syö kalaa 'J. eats fish')
(10e) Turkish: John balık ye-mi-yor.
J. fish eat-NEG-PRES(3SG)
(vs. John balık yiyor 'J. fish eats')
(10f) Japanese: John wa sakana wo tabenai.
J. TPC fish OBJ eat-NEG 5
(vs. John wa sakana wo taberu 'J. eats fish')
(10g) Welsh: Nid yw John yn bwyta pysgod.
NEG is J. in eat fish
(vs. Y mae John yn bwyta pysgod
DECL is J. in eat fish)
(10h) Russian: Ivan ne est rybu.
J. NEG eats fish
(vs. Ivan est rybu 'J. eats fish')
(10k) Guarani Juán nd-o'u-i pira.
(Tupi family): J. NEG-eats-NEG fish

Notice that in English there exists a special auxiliary verb to form negative sentences, the semantically main verb remaining uninflected. French and Guarani have the so-called discontinuous NEG around the verb (*ne . . . pas*); French shows also a morphosyntactic alternation between *de* and *du* depending on whether the sentence is negative or positive. In German, the NEG may be expressed by an adjectival inflected form; in Finnish, there is an inflected NEG verb whereas the lexical verb remains uninflected. Turkish agglutinates a NEG mark *-ma-/-me-* to the verbal accented stem, before other stem determinations (e.g.,*-me + yor > -miyor*). The Japanese NEG is a verbal negative form *-nai* suffixed to the indefinite verbal base; Welsh has a particle (*nid*) introducing NEG sentences parallel to the particles for declaratives (*y*) and interrogatives (*a*, as in *a mae John yn bwyta pysgod?*) so that we can say that NEG is a modality of the sentence. Among the eight languages under scrutiny, Finnish is, from the typological viewpoint, the nearest to English.

The phenomena emphasized here by no means exhaust the phenomenology of NEG sentences. Éwé (Kuwaa, Niger-Congo family) expresses NEG via a verbal prefix plus a strictly sentence-final clitic:

(11) Kofi yi vs. Kofi mé-yi o
K. went K. did not go

Dravidian languages have the possibility of a negative conjugation for every active, passive, 'neutral,' or even causative verb (recall the Welsh examples). In Tamil, the NEG mark is *-ā-*; but this *-ā-* agglutinating with the desinential vowel may disappear. The negative verb is therefore characterized by the absence of a specific mark (one of the not very common examples of unmarked forms for semantically and functionally marked meanings): *kāṇ-p-ēṇ* 'I shall see,' *kāṇ-ṭ-ēṇ* 'I saw,' but simply *kāṇ-ēṇ* 'I do not/I shall not/I did not see.' However, NEG forms usually contain one or more marks, in comparison with the corresponding positive sentence (cf., for instance, Examples (10c) and (10d)). In fact, from a philosophical point of view, it has been said (Henri Bergson) that, whereas the positive sentence has to be considered as a judgment, the negative is more complex, being a judgment on a judgment (see Example (1): [[it is not true

that]. . .]). Basically, the main strategies for sentence negation are as follows:

1. Morphological – a NEG mark (e.g., Examples (10g) and (10h)) that can be integrated in the verb (e.g., Examples (10e) and (10f)).
2. Morphosyntactic – NEG is expressed by a particular verbal cluster, with a negative auxiliary expressing tense aspect mood and person (e.g., Examples (10a) and (10d)); however, the verb categories may be distributed between the negative auxiliary and the main verb, as is the case for some Uralic languages. Purely syntactic strategies, such as specific word-order rules as in Kuwaa, are rather exceptional.
3. Lexical – as in Example (10c); special lexemes, different from the corresponding affirmative existential verb, can occur for the negative copula 'there is not, there does not exist' as in Turkish *yok* vs. *var*.

Considering the lexical strategy, compare Examples (12a) and (12b):

(12a) Ekmek yok.
bread there-is-not
'There is no bread.'

(12b) Ekmek var.
bread there-is
'There is bread.'

Östen Dahl published in 1979 a large study on the expression of NEG in around 240 languages; the study showed that NEG is most frequently expressed by either bound morphemes as part of the predicate or by separate particles. NEG auxiliaries make up only 16.7% of Dahl's sample, whereas the use of dummy auxiliaries, as in English, is quite rare. Dahl's (1979) results on the expression of NEG were as follows (the total is greater than 100% because a number of languages have more than one type of NEG):

1. Morphologically as part of the predicate, 45.0%.
2. Morphologically in an auxiliary verb, 16.7%.
3. By a separate negative particle (44.9%):
   a. In preverbal position, 12.5%.
   b. In pre-auxiliary position, 20.8%.
   c. Before verbal group, 2.1%.
   d. In postverbal position, 1.2%.
   e. In post-auxiliary position, 3.7%.
   f. In sentence-initial position, 0.4%.
   g. In sentence-final position, 4.2%.

Diachronic Evolution of NEG Markers

In several linguistic traditions, a trend can be observed that moves toward the use of an invariant NEG particle (preferably in preverbal position; see later). This is actually the most natural NEG strategy and comes nearest to the transparency ('diagrammatic') principle of optimization, i.e., 'one meaning: one form.' Thus Estonian does not inflect the NEG verb *ei* (3SG), which in this way approaches the uninflected particle construction type, drifting away from the auxiliary construction of the Finno-Ugric languages – that is, shifting from a morphological to a syntactic strategy (*John ei söö kala* 'John does not eat fish' but also with a subject in plural, *John ja Mary ei kohtunud koolis* 'John and Mary did not meet at school'; similarly, English *ain't* 'I'm not' has become a generalized NEG form).

A very interesting case is represented by the French-based creoles:

(13a) Louisiana: Mo kup pa and mo pa
me cut NEG me NEG
kup.
cut:
'I don't cut.'

(13b) Mauritius: Mo mõte pa pe travaj.
my watch NEG PROGR work
'My watch isn't working.'

(13c) Guyanese: Mo pa ka dromi.
me NEG FUT sleep
'I shan't sleep.'

There is a clear tendency to place the NEG marker (<French *pas*, postposed to the inflected verbal form: see Example (10b)) before the verb and also before tense and aspect markers (*pe*, *ka*). Exactly the same trend has been observed for Maghreb Arabic dialects, where the discontinuous NEG *ma* + verb + *-š* tends to be replaced by a simple preverbal NEG. It may be inferred from this evolution that Jespersen was right in stating (1917: 5) that there is "a natural tendency, also for the sake of clearness, to place the negative first, or at any rate as soon as possible, very often immediately before the particular word to be negatived (generally the verb)" – in other words, to construct negative sentences with the verb (i.e., the core of the predication) in the 'scope' of NEG. Danish, Norwegian, and Swedish are on the way to reintroducing preverbal NEG, and English-speaking children may produce, during their learning period, sentences with preverbal NEG (e.g., *No wipe fingers*), though their mother language has NEG after the inflected verbal form (*I do not wipe my fingers*). The same has been noticed also for Japanese adults learning English: though Japanese has NEG suffixed to the verb at the sentence end, as in Example (10f), in the first stages of their English instruction, Japanese learners formed in the first stages of their learning process sentences such as *I no want many children*,

I no like English, and also *He don't like it*, whereby *don't* is clearly perceived as a negation particle, simply a variant of no (similar to the usage of *ain't*). Also, from a diachronic point of view, postverbal NEG usually seems to imply preverbal NEG, via discontinuous NEG. French *pas* derives from Latin *passu*(*m*) 'step.' Together with other Romance NEG particles, such as French *goutte* 'drop,' Italian *mica* 'crumb,' Catalan *cap* (<Latin *capu*(*t*)) 'head,' Sursilvan Romantsch *buc*(*a*) (< Latin *bucca* 'cheek'), etc., *pas* represents a clear instance of a lexeme having developed to NEG marker (first in postverbal position). The original meaning of *pas* (and that of *goutte*, *cap*, etc.) was not at all negative – rather, it was the 'measure' object of the verb occurring in postverbal position, as expected in an subject-verb-object (SVO) languages, such as Late (Vulgar) Latin: *non vado passum* 'I do not proceed a step'(> French [*je*] *ne vais pas*), *non bibo guttam* 'I do not drink a drop' (> French [*je*] *ne bois goutte*). We find the same evolution in the already mentioned Arabic discontinuous NEG: *ma-katabuu-š* (Cairo Arabic) 'they did not write,' wherein the second NEG form derives from the indefinite accusative *šay ʔ*(*an*) 'thing' – thus 'not + verb + a thing.'

By occurring mostly in sentences with negative meaning, *pas*, *goutte*, *šay ʔ*(*an*), etc. assumed negative value *per se* and became negative polarity items (NPIs), no longer bound to a semantically congruent verb. Generalization of *pas* as NEG particle gives *je ne vois pas*. NPIs can thus occur only in negative contexts. But discontinuous constructs such as *ne* ... *pas* are marked constructions and tend to be avoided: only 17% of the languages (usually of the SVO type) have this kind of NEG. Actually, the preverbal, weakly articulated part of the French negative construct (i.e. [n]) is redundant: *je ne vais pas* > colloquial *je vais pas*. The NPI may also be emphatically reinforced (*pas* > *pas du tout, literally 'not at all') and become in turn redundant (pas du tout* > *du tout), as in Example (14):*

(14) Croyez-vous que je vous blâme? Du tout.
'Do you believe that I blame you? No, I don't.'

Schematically, the so-called 'NEG cycle' may be represented as follows (see Schwegler, 1988):

(15) ne + verb > ne + verb + pas > verb + pas (> pas du tout > du tout)

The same holds true also for English and German, in which *not* and *nicht* derive from *naught*, *nought* < Old English *na-wiht* and, respectively, Old High German *niowiht*, literally 'no-whit, no-thing':

(16) English: ne + verb > ne + verb + not > verb + not

Syntax of Negation: NEG Quantifiers

There is an important topic to be dealt with, partly related to what has been said so far about the NPIs, namely, the so-called permeable and impermeable negation, which is relevant to the syntax of NEG. The term 'permeable/impermeable negation' was suggested by Tesnière (1966: 235f.). There are languages that repeat the negation on every element of the sentence that can be negated: In Russian we find

(17a) Nikto ni s kem ni
Nobody NEG with anybody NEG
o čëm ne govoril.
about anything NEG spoke
'Nobody spoke with anybody about anything.'

or

(17b) Nikto nigde nikogda ètogo ne skazal.
Nobody nowhere never this NEG said

On the other hand, in (Standard) Latin we find

(18a) Nemo hoc unquam dixit.
Nobody this ever said

or

(18b) Numquam hoc ullus dixit.
Never this anybody said

with just one negated element. NEG is not 'permeable.' The same holds for English (recall the counterexample from substandard English, *I don't see nothin' nowhere*):

(18c) Nobody ever said this.

or

(18d) Never did anybody say this.

Between the two poles of highest permeability (as in the Russian examples) and highest impermeability (as in the Latin and English examples) there are intermediate stages along a 'continuum':

(19a) French: Pas une fois il n'a adressé la parole à personne.
NEG a time he NEG has spoken to nobody
'He has never spoken to anybody.'

vs.

(19b) Italian: Mai una volta ha rivolto la parola ad alcuno/nessuno.
Never a time has spoken to somebody/nobody
'(S)he has never spoken to anybody.'

and not

	PERS.ANIM.PRON. &	NTR.PRON. >	TEMP. >	LOC. >	OTHER ADVs
Russian:	*nikto*	*nicto, ničego*	*nikogda*	*nigde*	*nikak*
English:	*nobody*	*nothing*	*never*	*nowhere*	*(no way)*
Modern Greek:	*kaneịs*	*tịpote*	*poté*	*pouthenà*	
Spanish:	*ninguno*	*nada*	*nunca*		
Welsh:	*neb*	*dim (byd)*			

Figure 1 Hierarchy of negative quantifiers: personal animate pronouns and neuter pronouns > temporal > locative > other adverbs.

(19c) *Mai una volta non ha rivolto. . .

Italian uses a NEG (or two) less than French does.

Returning to Examples (18a) and (18b), *unquam* and *ullus* are quantifiers (an adverb and, respectively, a pronoun) that usually occur in the scope of NEG and become therefore NPIs. But NPIs, which do not (yet) have full negative value, must be preceded by a clear NEG mark, as shown for French in Example (20a):

(20a) Jean n'a pas dormi de la nuit.
'John hasn't slept all the night long.'

Here, *de la nuit* is on the way to acquiring negative value. However, it is not (yet) possible to say

(20b) *Jean a dormi de la nuit.

without a clear NEG mark before the NPI (and the verb). On the contrary, it is possible to say

(21) Je n'imagine pas que Jean ait dormi de la nuit.
'I do not imagine that J. has ever slept during the night.'

since the NPI appears in a sentence that is subordinated to a negative main sentence. The general rule for these quantifiers is therefore that in negative sentences an element clearly showing negative value must have in its scope (i.e., must precede) the NPIs and the verb. Compare two Italian sentences, both meaning 'Nobody/no people came':

(22a) Nessuno venne.
(22b) Non venne nessuno.

If an NPI comes first in a sentence, then it means that its negative value has already fully developed, and no other NEG is strictly required before verb. It has already been stated that there may also be languages that do not have a lexeme for negative quantifiers, as in the Hindi sentence in Example (23), which has the same meaning as the Italian sentences in Examples (22a) and (22b) (see also Examples (8a) and (8b)):

(23) Koî nahî âya thâ.
somebody NEG come was

Note that NEG precedes the verb and gives a negative meaning to the sentence.

Four main types may be distinguished for quantifiers in negative sentences: (1) existential quantifier + NEG, as in Hindi (Example (23)); (2) 'neutral' (not negative) quantifier + NEG, as in English *John did not see anybody*; (3) NEG + negative quantifier, as in Italian *Giovanni non vide nessuno* (same meaning as the previous English sentence); and (4) negative quantifier without NEG, as in German *Hans hat niemanden gesehen* (same meaning). Otherwise, languages may appeal to nonexistential constructions; e.g., in Modern Standard Arabic:

(24) Fī bilādi-nā laysa dayfan.
in town 1PL NEG:EXIST visitor
'Nobody is a stranger in our town.'

Cross-linguistic comparison hints at the hierarchy of negative quantifiers, shown in **Figure 1**, when they exist (the preceding quantifier types 3 and 4). Moreover, inherently negative quantifiers may be restricted to some position. The Australian language Tiwi has *kar ∂kuwani* 'no-one' and *karθkamini* 'nothing,' which are restricted to subject position (see Payne, 1985: 238).

Another phenomenon of the syntax of negation that deserves to be dealt with and can be explained in terms of discourse pragmatics is the so-called NEG-raising:

(25a) John wants the secretaries not to leave early.
(25b) John does not want the secretaries to leave early.

These sentences are not completely synonymous. There is indeed a semantic-pragmatic difference. Example (25b) indicates a lesser degree of control on the part of John over the state of affairs, whereas Example (25a) states as a matter of fact what John's firm will is. Moreover, the so-called raising of NEG we may observe in Example (25b) is not possible with every verb. There are semantic constraints: only verbs that admit the possibility of being controlled by the 'subject' (first actant), such as *think* or *want*, may let NEG 'leak' into the main sentence. This is not possible with a verb such as *fear*, although it and *think* belong to the same class of opinion verbs: the sentence

(26a) I fear that he will not arrive tomorrow.

has a completely different meaning than

(26b) I do not fear that he will arrive tomorrow.

Now, a transformation rule (here 'move NEG') governed by semantic criteria is not easily accepted in the generative theory. Moreover, since there is no hint of any trace whatsoever left by the NEG in its original position before the movement, we cannot decide whether NEG has been 'raised' to the main sentence in Example (25b) or 'lowered' to the subordinate clause in Example (25a). There seems to be no use in adopting the generative point of view. The position of NEG is determined by the speaker's intentions of focusing this or that part of the message (note the different message organizations of Examples (28a) and (28b)).

Pragmatics of Negation

As may be argued from the historical evolution sketched in the previous section, pragmatics plays an important role in NEG strategies, especially because of the wish to reinforce the negative value of the utterance. NPIs such as *pas*, *goutte*, etc. are emphasizing expressions that originally served to underline the negative meaning of the sentence and then became grammaticalized as NEG markers. An example in English is the statement and response *I heard what you said – The deuce you did!* ('You didn't at all') (Jespersen, 1917: 33). If the 'natural' position of NEG is the preverbal one, so that the verb lies in the scope of NEG, why is it that there are languages, including German, Brazilian Portuguese, some Italian dialects, etc., that have postverbal NEG? The origin of German *nicht* and its postverbal position have already been discussed. In Brazilian Portuguese, or other Romance traditions, this is (equivalent to Examples (10a)–(10f))

(27a) O João (não) come peixe não.

Compare also the very similar Afrikaans construction

(27b) Jan eet nie vis nie.
J. eats NEG fish NEG

in which the first NEG comes after the verb, according to the Germanic pattern. The first *não* may be omitted. Postverbal *não* is, with few exceptions, sentence-final. However, in subordinate clauses, we do not find sentence-final NEG:

(28a) Eu imagino que você não tem dinheiro.
'I imagine that you not have money.'

and not

(28b) *Eu imagino que você tem dinheiro não.

Note also in

(28c) Eu não imagino que você tem dinheiro não.
'I do not imagine that you have money.'

that the subordinate clause is not negated and the final *não* represents the second NEG marker of the main verb, as in Example (27a). This is also exactly the case in Afrikaans:

(29) He het nie gesê, dat hy hierdie
he has NEG said that he this
boek geskrywe het nie.
book written has NEG
'He has not said that he has written this book.'

All this hints at an 'afterthought' strategy as the origin of the sentence-final NEG, a kind of comment after an intonational break that later disappeared when the final position became grammaticalized as regular. Compare for this kind of pragmatic discourse strategy substandard English *I'm not gonna say it, nah*, or French *J' vais pas le dire, non*.

The afterthought strategy may account for sentence-final NEG occurring also in SVO languages such as Portuguese. This is not the only possible explanation, however. It is clear that diachronically, there is a great difference between the *pas* or *not/nicht* cases (ancient postverbal 'measure objects') and that of Portuguese *não*. Synchronically, however, they belong to the same type of NEG. Many different sources may have contributed to the origin of postverbal (sentence-final) NEG. A large-scale analysis of all of the languages of the world that have sentence-final or postverbal NEG remains, however, to be done. In any case, it seems that word order does not play a decisive role in assigning to NEG its position in the sentence – contrary to what was thought in the first attempts at typologizing according to the word-order types (see Lehmann's (1978: 18) 'structural principle'). Rigid and consistent SOV languages should always have NEG after the verb, as is the case for Sinhalese (SOV):

(30a) Jōn ballavə̄ däkke nä:.
J. dog saw NEG
'John didn't see the dog.'

In rigid and consistent VSO languages, NEG should always come at the beginning of the sentence, as in Irish:

(30b) Ní fhaca Seán an madadh.
NEG saw John the dog
'John didn't see the dog.'

But this is not always the case. In Dahl's language sample, only Bengali and Tamil are in fact quoted as

having the order SOV + NEG, wherein NEG is an uninflected particle that seems to have developed out of auxiliary verbs (see Dahl (1979: 94) and Appendix A therein). This kind of historical development for syntactic negation has to be noticed as another possible diachronic explanation for sentence-final/postverbal NEG.

Prohibitive NEG

The difference between declarative and prohibitive NEG was indicated previously. Prohibitive is linked to imperative modality, which is often expressed by a different verbal form – namely, a nonreality form (imperative, subjunctive, optative, etc.). There are languages that make use of the same NEG marker for both, and languages that distinguish between them:

(31) You do not eat fish. [declarative]

as well as

(32) Do not eat fish, John! [imperative]

The distinction rests in this case on the opposition between indicative form with obligatory pronoun, and imperative form without pronoun. On the other hand, we find (with the same meaning as in Example (31) in Modern Greek the sentence

(33) (Su) dén trôs psári.
you NEG eat:2SG fish

versus the sentence

(34) Mēn pernâs, Giánnē.
NEG cross:2SG VOC
'Do not cross, John!'

Notice that in Modern Greek, indicative and subjunctive endings may not be distinguished: in this case, the opposition is based solely on the distinction *de*(*n*)/*mē*(*n*). Italian offers the reverse strategy: whereas NEG remains unchanged, the second-person singular imperative has a special form:

(35) Giovanni, non-attraversare.
J. NEG-cross:2SG.IMPERAT

versus

(36) Giovanni non attraversa.
J. NEG cross:3SG.INDIC
'John does not cross.'

Different verbal forms together with different NEG markers are found redundantly in Examples (37) and (38) (Ancient Greek) and Examples (39) and (40) (Latin):

(37) Mḗ, m' eréthize.
NEG me make.angry:2SG.IMPERAT
'Don't make me angry.'

(38) Ou m' erethízeis.
NEG me make.angry:2SG.INDIC
'You do not make me angry.'

(39) Ne cantes.
NEG sing:2SG.SUBJ
'Do not sing.'

(40) Non cantas.
NEG sing:2SG.INDIC
'You do not sing.'

In some cases, there may be just an intonation difference:

(41) Jean ne traverse pas.
'John is not crossing.'

versus

(42) Jean, ne traverse pas!
'John, do not cross!'

The cognitive-behavioral difference between declarative and prohibitive negation is basic, and every language has a means to express the functional opposition. In order to show the large variety that is possible, the following scale for marking prohibitive negation could be tentatively drawn (see Bernini and Ramat, 1992: 105):

Intonation only (Example (42)).
Morphosyntax (Examples (31) and (32)).
Different markings on NEG (Examples (33) and (34)).
Different markings on verb (Examples (35) and 36)).
Different marking on both NEG and verb (Examples (37)/(38) and (39)/(40)).
Different lexical choice (Examples (43) and (44)).

(43) Latin: Noli me tangere.
don't want:2SG.IMPER me touch
'Don't touch me.'

(44) Welsh: Peidiwch â siarad!
stop:2PL with talk(ing)
'Do not talk!'

Negation: Philosophical Aspects

Most people, if they think of negation at all, have in mind something fairly simple, namely classical (or Boolean) negation. Classical negation is an operator that works as a sort of toggle switch on propositions or predicates: When applied to a proposition with the semantic value 'True,' it returns a proposition with the semantic value 'False' and vice versa. When applied to a predicate true of some collection of individuals (of some type), it returns another predicate that is true of exactly those individuals (of that type) for which the original failed to hold. If one regards relations as predicates that apply to pairs (triples, quadruples, etc.), and considers pairs (etc.) as individuals of a higher type, one has a general-purpose notion of negation. Make the convenient assumption that every proposition has exactly one of the two truth values just mentioned, and that predicates have sharply defined domains of application and sharp boundaries within those domains, and nothing more needs to be said.

It is increasingly rare to find philosophers of logic who are happy with the idea that this is the whole story about negation. Most philosophical issues regarding negation are illuminated by considering some reasons for their dissatisfaction. However, first it is useful to consider the question of what properties an operator needs to have to count as a genuine negation. This is surely the fundamental philosophical question about negation, and it must be answered before one can adjudicate the justice of the most common complaint raised against various nonclassical negations – that they are not really negations at all.

To keep the discussion manageably brief, we gloss over some philosophical niceties. For instance, we shall move freely between negations of propositions and of predicates when it makes examples clearer, although some contend that these might not involve the same operator. We also mostly ignore the question of whether negation is an operation on sentences (and predicates) or on propositions (and properties), thereby pretending some issues are simpler than they really are. We use the symbol '¬' for the negation operator.

Possible Properties of Negation

Probably the strongest opinion most people would have about negation, is that for any sentence P, P and ¬P cannot both be true. If ¬P is really the negation of P, then it must be incompatible with P. However, one must remember the distinction between negations and mere contraries. For if P is '*x* is white,' then '*x* is black' is certainly incompatible with P – it is a contrary of P – but it is not ¬P. For, surely, if the *x* in question is orange, ¬P must come out true. However, '*x* is black' does not. One natural way to think about ¬P is as the weakest proposition that is incompatible with P. In our example, ¬P is a proposition implied by any proposition that rules out *x* being white, perhaps equivalent to '*x* is black or *x* is orange or *x* is yellow . . . ,' running through all the nonwhite colors. Thinking of negation in this way, and assuming that if A is incompatible with B then also B is incompatible with A (which not everyone grants, for reasons we will not pursue), is equivalent to assuming that negation obeys the following law: A implies ¬B if and only if B implies ¬A. (In this view, A implies ¬B exactly when A is incompatible with B. If this means also that B is incompatible with A, this happens exactly when B implies ¬A.) This is the characteristic law of so-called 'minimal negation,' and almost all candidate negations satisfy it.

Of course, the classical negation of P is not merely the weakest proposition contrary to P (although it is that) but also satisfies many additional laws. Most significantly, ¬P must be a complement of P; that is,

not only must (P and ¬P) be a logical falsehood but also (P or ¬P) must be a logical truth. That ¬P satisfies the latter condition for any P is called the law of excluded middle and is close enough kin to the principle of bivalence (for any P, P gets exactly one of two truth values, and so ¬P gets the other) that we can ignore the difference here. Other important principles that hold for classical negation include the four De Morgan laws: ¬(P and Q) implies (¬P or ¬Q) and vice versa, and ¬(P or Q) implies (¬P and ¬Q) and vice versa. The logical principle sometimes called 'explosion' is valid for classical negation: Everything follows from a contradiction (i.e., a pair P, ¬P). In the presence of explosion, the law of excluded middle is equivalent to the principle of double negation elimination: ¬¬P implies P, which therefore also holds for classical negation.

We can now efficiently describe the most discussed nonclassical negations. (The philosophical significance of these distinctions should become clear in later sections.) If a minimal negation also satisfies explosion, we have an 'intuitionistic negation.' On the other hand, if a minimal negation satisfies the four De Morgan laws, we have what is sometimes called 'Ockham negation.' This unfortunate name is needed because common usage has it that a 'De Morgan negation' is an Ockham negation for which also the principle of double negation elimination holds. An 'orthonegation' is both intuitionistic and De Morgan. Classical negation is orthonegation in a logical system in which 'and' distributes over 'or' and vice versa. Nonclassical orthonegations show up in nondistributive quantum logics. Distributivity guarantees that every proposition has at most one complement, but we will ignore the differences between classical and orthonegation here.

One sometimes sees discussion of 'subminimal negation.' It is characterized by the condition that the following principle of contraposition must hold: If A implies B, then ¬B implies ¬A. Every minimal negation satisfies this principle, but not conversely. Although most would accept that this is a necessary condition for an operator to count as a negation, it seems insufficient because there are operations in natural language that seem to be subminimal negations that are difficult to take seriously as negations. Skipping details, an example is the operation we might call 'few N': If '*x* is a fish' implies '*x* has gills,' then 'Few dogs have gills' implies 'Few dogs are fish,' and similarly for any similar example, but 'few N' looks even less like a negation than any mere contrary forming operator. Sometimes, especially in programming applications, one sees operations called 'negations' that are not even subminimal (e.g., some 'negation as failure' operators). We shall not consider these operations.

Negations, Consistency, and Paradoxes

We begin with some responses to the so-called 'semantic paradoxes,' especially the liar paradox. Consider (L):

(L): L is false.

(L) certainly looks to be true if and only if it is false. Nonclassical negations often appear in proposed solutions to such paradoxes; we briefly consider a simple example later. For now, we consider so-called 'dialetheism.' Dialetheists hold that some sentences P are both true and false (and so that both P and ¬P are true, if ¬P is true whenever P is false). Sentences such as (L) are their prime candidates for this status. In barest outline, they argue that a century of intense effort aimed at explaining what is going on with (L) while preserving consistency has led, at best, to solutions that are plausible only to those who formulate them. The mistake, they suggest, is in trying to preserve consistency.

One obvious objection to dialetheism is that if P and ¬P can both be true at the same time, the ¬ symbol is not functioning as a negation. In such a case, ¬P is not even a contrary of P, violating the most basic intuition about negation. One dialetheist response is that in many dialetheic logics, ¬(P and ¬P) is a necessary truth for all P, even those where P is both true and false. They suggest that this captures the truth behind the idea that negations are contraries. It is just a surprising development that (P and ¬P) is also true in some cases.

Dialetheist must defend a negation for which explosion is not valid, on pain of holding that all statements are true. Others defend nonexplosive logics, called 'paraconsistent' logics, for a variety of other reasons. For instance, correct reasoning from a set of beliefs seems to be quite constrained, despite the fact that most sets of beliefs are inconsistent. However, if explosion were valid, correct reasoning from an invalid set would presumably be completely unconstrained. Paraconsistent systems often have De Morgan negations. Philosophical debates about the acceptability of such logical systems often turn on the surprising cost of giving up explosion. Consider the following: If both P and ¬P are true, we may choose an arbitrary Q and infer (P or Q) from P and then by so-called 'disjunctive syllogism' infer Q from (P or Q) and ¬P – so we seem to have shown that explosion is a correct derived rule of inference. To

block this argument, it seems we must: change our rule of 'or introduction'; hold that the result of stringing together deductively valid inferences is not always valid; or declare that disjunctive syllogism is not valid, despite appearances to the contrary. Many philosophers regard any of these as a higher price to pay than accepting the counterintuitive explosion rule.

Consider next the 'paradoxes of vagueness.' For concreteness, let P(n) stand for 'there are more than n seconds in my childhood.' It seems we have good reason for accepting (i) P(0) is true; (ii) for any n, if P(n) is true then so too is P($n + 1$) (since one certainly does not change from a child to a nonchild from one second to the next); and (iii) for a sufficiently large m, ¬P(m). However, P(m) follows from (i) and (ii). In classical logic, rejecting (ii) implies that there is a number n such that one is a child for n seconds, but 1 second later one is not. However, in many logics this does not follow. In particular, many logics that reject the law of excluded middle avoid this conclusion. Indeed, the phenomenon of vagueness is thought by some to pose a more direct challenge to classical negation. The minimal logic condition applied to predicates instead of propositions means that ¬P(x) picks out the property whose extension is as large as possible while remaining disjoint from the extension of P(x). However, if P(x) is vague, why should we suppose that all relevant x fall either in P(x) or in ¬P(x)? To suppose there is always such a property seems to be assuming that every property has sharp boundaries, which seems to amount to saying that there are no vague properties.

Finally, consider the 'knowability paradox': in classical logic, given some seemingly innocuous presuppositions about the nature of necessity and of knowledge, it follows from

(AR) all truths are *knowable*

that

(AK) *all truths are known.*

(Here is one set of assumptions suffices: knowledge distributes over conjunction; what is known is true; what is proved to be a theorem is thereby proved to be necessarily true; and if (necessarily ¬P) then ¬(possibly P).) Many philosophers are inclined to accept (AR), at least for certain domains of discourse, but almost none are tempted by (AK). However, the argument that (AR) implies (AK) depends essentially on double negation elimination. Hence, one can block the argument if negation is not De Morgan (e.g., if it is intuitionistic). Of course, to argue for this requires, if this solution is not to be merely *ad hoc*, giving independent reasons for rejecting classical negation – one could, after all, have rejected one of the plausible assumptions about necessity or knowledge instead, if blocking the paradox were alone sufficient to motivate such reformation of philosophical presuppositions.

More Than One Negation?

Some authors argue that it is a mistake to think that the same operation is involved in forming the negation of sentences and properties, something we have assumed without question. For instance, arguably the logical behavior of 'x is not-P' differs from that of 'it is not the case that x is P'; for example, x will be not-white only if x is definitely not white (i.e., is not a boundary case of whiteness), whereas if x is a boundary case, then it is not the case that x is white, but if the same operator is at work in both claims they should be equivalent.

Nonclassical languages sometimes suffer from a lack of expressive power if there is only one negation, in the sense that that negation leaves us unable to express what we seem able to express in natural language. For instance, ¬P, using intuitionistic negation, says that P is, in some suitable sense, impossible. (In both minimal and intuitionistic logic, ¬P is often defined as 'if P, then absurdity results.' To see why this makes sense, look again at the characterization of minimal negation in the first section and note that adding explosion merely makes the consequences of absurdity particularly dire.) One loses the link to impossibility in De Morgan (and so classical) negations. For instance, with De Morgan negation one can infer from ¬(P and Q) that (−P or −Q), but it certainly does not follow from the impossibility of P and Q being jointly satisfied that one of P and Q must be impossible. This matters because although one cannot intuitionistically derive (AK) from (AR), one can derive, for any P,

(∗)¬(P and ¬(It is known by someone at some time that P))

which is okay because this means only that it is impossible for P to be true and at the same time it be impossible for anyone to know it, which should follow from AR. However, if intuitionistic negation is the only one available it is difficult to see how one might express the claim that 'some claims are true but never known' since, as we have seen, (∗) says something quite different. The obvious response is to argue that some other negation, compatible with but distinct from intuitionistic negation, is involved in expressing it. (Note that this other negation must be nonclassical, for if P has both a classical

and intuitionistic negation, they are the same proposition, viz. the weakest proposition incompatible with P, so classical and intuitionistic negation cannot exist as distinct negation operators for the same class of sentences.) Similarly, if the only negation is the dialethic negation, how can we express things like 'P is true, and is not also false'?

Negation and Denial

Why not say, "The problem with (L) is that it *does not express a proposition*, and so *fails to have a truth value*? Since it fails to have a truth value, so too does its negation – (L) and it's negation fall into a *truth value gap*." One reason is that this seems not to work for the so-called 'strengthened liar' (SL):

(SL) SL is not true.

For if (SL) is neither true nor false, then it is not true, and so should be true.

Notice that in our discussion of (L) we suggested that if P falls into a truth value gap, so too does ¬P, but in discussing (SL) we assumed that if P falls into a gap, not-P is true. If what we have said in both cases were correct, 'not' in the (SL) case is expressing some different notion of negation than is expressed by the negation sign in the (L) case, and we seem to be stuck with an ambiguity in the meaning of 'not.' It has been suggested, though, that 'not' is pragmatically, rather than semantically, ambiguous: It is sometimes used to form negations, and at other times it is used to deny a claim. When we say that (SL) is not true, we are denying (SL) without thereby asserting its negation. However, we only fall back into paradox if we assert the negation of (SL). What makes this proposal philosophically contentious is that the prevailing view, going back at least to Frege, is that denial is not a separate speech act but is equivalent to the assertion of the negation of the claim in question.

Classical and Nonclassical Negation

In logic, negation is an operation that applies to a sentence (or more generally a formula), thus yielding a new sentence. The sentence thus obtained is called the negation (or in some authors the denial) of the sentence negated. The negation sign is a logical operator, which is written in front of the relevant formula. The negation of a sentence φ is – depending on the notation convention adopted – written as $\neg\varphi$, $\sim\varphi$, $-\varphi$, $\bar{\varphi}$ or $N\varphi$. In Frege (1879), we find a small vertical stroke attached to the lower side of the content stroke. In his notation, the judgment that φ is not the case thus comes out as $\vdash\!\!\neg\varphi$.

In a classical two-valued logic (which allows exactly two truth values and moreover takes for granted that every sentence has a truth value), there is only one possible semantic definition of negation: the negation operator is a function that maps truth to falsity and falsity to truth. We may, however, deviate from classical semantics in various ways. One way is to question the assumption that every sentence has a truth value, another way is to allow for more than two truth values. This comes down to rejecting the principle of bivalence. The first strategy gives rise to so-called partial logics, the second to multivalent logics. A partial logic thus allows a sentence to have no value and it is common to refer to this third possibility as a truth value gap. In multivalent logics, we may define several negation operators; what their truth tables look like will depend on the intended interpretation of the nonclassical values. In a three-valued logic, a sentence that is not true may either be false or have the third truth value. In this view, falsity is a subcategory of what is not true. An alternative account takes the third value as a special way of

and intuitionistic negation, they are the same proposition, viz. the weakest proposition incompatible with P, so classical and intuitionistic negation cannot exist as distinct negation operators for the same class of sentences.) Similarly, if the only negation is the dialethic negation, how can we express things like 'P is true, and is not also false'?

Negation and Denial

Why not say, "The problem with (L) is that it *does not express a proposition*, and so *fails to have a truth value*? Since it fails to have a truth value, so too does its negation – (L) and it's negation fall into a *truth value gap*." One reason is that this seems not to work for the so-called 'strengthened liar' (SL):

(SL) SL is not true.

For if (SL) is neither true nor false, then it is not true, and so should be true.

Notice that in our discussion of (L) we suggested that if P falls into a truth value gap, so too does ¬P, but in discussing (SL) we assumed that if P falls into a gap, not-P is true. If what we have said in both cases were correct, 'not' in the (SL) case is expressing some different notion of negation than is expressed by the negation sign in the (L) case, and we seem to be stuck with an ambiguity in the meaning of 'not.' It has been suggested, though, that 'not' is pragmatically, rather than semantically, ambiguous: It is sometimes used to form negations, and at other times it is used to deny a claim. When we say that (SL) is not true, we are denying (SL) without thereby asserting its negation. However, we only fall back into paradox if we assert the negation of (SL). What makes this proposal philosophically contentious is that the prevailing view, going back at least to Frege, is that denial is not a separate speech act but is equivalent to the assertion of the negation of the claim in question.

Classical and Nonclassical Negation

In logic, negation is an operation that applies to a sentence (or more generally a formula), thus yielding a new sentence. The sentence thus obtained is called the negation (or in some authors the denial) of the sentence negated. The negation sign is a logical operator, which is written in front of the relevant formula. The negation of a sentence φ is – depending on the notation convention adopted – written as $\neg\varphi$, $\sim\varphi$, $-\varphi$, $\bar{\varphi}$ or $N\varphi$. In Frege (1879), we find a small vertical stroke attached to the lower side of the content stroke. In his notation, the judgment that φ is not the case thus comes out as $\vdash\!\!\neg\varphi$.

In a classical two-valued logic (which allows exactly two truth values and moreover takes for granted that every sentence has a truth value), there is only one possible semantic definition of negation: the negation operator is a function that maps truth to falsity and falsity to truth. We may, however, deviate from classical semantics in various ways. One way is to question the assumption that every sentence has a truth value, another way is to allow for more than two truth values. This comes down to rejecting the principle of bivalence. The first strategy gives rise to so-called partial logics, the second to multivalent logics. A partial logic thus allows a sentence to have no value and it is common to refer to this third possibility as a truth value gap. In multivalent logics, we may define several negation operators; what their truth tables look like will depend on the intended interpretation of the nonclassical values. In a three-valued logic, a sentence that is not true may either be false or have the third truth value. In this view, falsity is a subcategory of what is not true. An alternative account takes the third value as a special way of

being not false. Finally, we may see the third value as independent of both truth and falsity. We thus may interpret the third value as a special way in which a sentence may go wrong and different interpretations will generally give rise to different truth tables.

Nonclassical accounts of negation go back to Aristotle. Aristotle argued (in his famous 'sea battle' argument) that if the sentence *There will be a sea battle tomorrow* were now either true or false, we would be committed to fatalism. Lukasiewics concluded that such contingent future tense sentences are neither true nor false and consequently rejected bivalence. He introduced a third truth value to be interpreted as indeterminate or contingent, which naturally yields a truth table that maps truth to falsity, falsity to truth, and the third value to the third value. The Russian logician Bochvar gave another motivation for three-valued logics, arguing that it allows us to avoid logical paradoxes. Other writers have given various linguistic arguments for such deviations from classical logic. Three cases that received quite a bit of attention in the linguistic literature are category mistakes, vagueness, and presupposition failure.

Examples of category mistakes are Carnap's *Caesar is a prime number* or Chomsky's *Colorless green ideas sleep furiously.* Such sentences do not ascribe properties to things they do not have (which would result in falsity), but properties they cannot possibly have, thus yielding absurdity. And, since this holds for both the unnegated sentence and its negation, it gives a truth table that maps the third value (interpreted as nonsensical) on itself. The problem is closely related to the problem of presupposition failure (see below).

Vague predicates comprise predicates such as *small*, *beautiful*, *long*, etc., that is predicates that apply to a thing or set of things to a certain extent. In some cases, it is simply unclear whether a predicate applies to an object. An example is Austin's *France is hexagonal*. Vague terms admit borderline cases, cases in which it cannot be uniquely determined whether a concept falls under the term or not. Three-valued logics are not of much help in solving the problem, since they replace the classic dichotomy between true and false with a strict trichotomy between true, false, and indeterminate, which yields results that are equally counterintuitive as those that result from a bivalent approach.

The most popular accounts are the so-called fuzzy logics introduced in the mid 1960s (Zadeeh, 1965) and the method of supervaluations (Van Fraassen, 1966). Fuzzy logics accept an infinite number of truth values (a real number in the interval [0, 1]). The idea is that the closer the value is to 1 the 'truer' the sentence is. The value of a negated sentence is taken to be 1 minus the value of the unnegated sentence. Assuming that vague sentences get their value somewhere in the middle of the interval, it follows that if a sentences is maximally vague, so is its negation. The same holds for conjunctions and disjunctions of vague sentences. Fuzzy logics have been objected to on a number of counts. Most importantly, people have objected to the artificiality of assigning precise numerical values to the degree to which an object is small or beautiful. An alternative account is found in the method of supervaluations. Supervaluations – which were originally developed to account for presupposition failure – differ from multivalent logics in that they accept only two truth values but allow truth-value gaps. Just as in fuzzy logics, the negation of a vague sentence will come out as vague; but in contrast to fuzzy logics, formulas that are classically valid (or contradictory) will always come out as true or false no matter what the values are of their atomic components. A comparison between the approaches and a linguistic application is found in Kamp (1975).

Some of the best-known deviations from classical logic originate from presupposition theory. For Frege (1892) and Strawson (1952), presuppositions act as preconditions a sentence should satisfy in order to be true. Strawson and many other authors took preservation under negation as the defining characteristic. Thus (1b) seems to suggest as strongly as its unnegated counterpart (1a) that (1c) is true.

(1a) The king of France is bald.
(1b) The king of France is not bald.
(1c) France has a king.

This phenomenon is general and seems to hold for all other lexical items that are said to induce presuppositions:

(2a) John quit smoking.
(2b) John didn't quit smoking.
(2c) John used to smoke.

Inspired by Strawson the so-called neo-Strawsonians turned preservation under negation into a definition of semantic presupposition:

(3) A sentence φ presupposes ψ just in case
(i) φ entails ψ; and
(ii) $\neg\, \varphi$ entails ψ.

If we assume that negation maps truth to falsity and vice versa and, if we also adopt the standard definition of semantic entailment (φ entails ψ iff for any model M if $[[\varphi]]^M = 1$ then $[[\psi]]^M = 1$), (3) is equivalent to

(4) φ presupposes ψ just in case
(i) in any model in which $[[\varphi]]^M = 1$ it holds that $[[\psi]]^M = 1$; and
(ii) in any model in which $[[\varphi]]^M = 0$ it holds that $[[\psi]]^M = 0$.

The latter simply comes down to the idea that if a sentence φ presupposes a sentence ψ, φ cannot have one of the classical values true or false, unless ψ is true. In a classical two-valued logic, this would predict that sentences can only presuppose tautologies. This forces the theorist to either allow for truth-value gaps or alternatively to introduce a third value to account for presupposition failure. If we allow truth-value gaps, compositionality predicts that if the unnegated sentence has no value, its negated counterpart will not have a value either. In a three-valued logic, this is captured by adopting the following truth table for negation (* indicates the third value):

(5)

φ	$\neg\varphi$
1	0
0	1
*	*

In conjunction with definition (3), this correctly predicts that presuppositions are preserved under negation.

Russell pointed out that (1b) has a second reading according to which this sentence is true simply because there is no king of France. In his analysis, the difference between the two readings is cashed out in terms of scope. In addition to the 'standard' interpretation, which is obtained by giving negation narrow scope and thus yields the formula (6a), we obtain the second reading by giving the negation scope over the full formula as in (6b):

(6a) $\exists x \forall y[[KF(x) \leftrightarrow x = y] \wedge \neg\ Bald(y)]$
(6b) $\neg\ \exists x \forall y[[KF(x) \leftrightarrow x = y] \wedge Bald(y)]$

This retains classical two-valued negation and eliminates presuppositions. It also illustrates the idea, found in Frege, that negation can always be represented as the standard operator suitably placed in the logical representation.

Russell's theory eliminates presuppositions. However, the difference between a presupposition preserving and presupposition canceling interpretation can also be obtained in a three-valued logic by defining a second negation operator $\sqsupset \varphi$ that maps the third value onto truth:

(7)

φ	$\sqsupset\varphi$
1	0
0	1
*	1

We perceive two kinds on nontruth. Nontruth as plain falsity and nontruth as a result of presupposition failure. The operator given in (5) is known as the weak Kleene-negation or the internal Bochvar connective; the operator defined in (7) is the same as the external Bochvar negation (also called the denial operator).

Negation and Polarity

Natural language contains a class of expressions whose distribution is limited to contexts that feel negative. Such items are called negative polarity items (NPIs). NPIs come in various types and syntactic categories: quantifiers and quantifier phrases (*any, any book*), verbs (*bother to*), factives (*mind that, matter that*), adverbs (*ever, yet*), prepositions (*until*), modals (*need*), idioms (*give a damn, lift a finger*), and many more. Thus the a sentences below, where we find the NPIs *any* and *ever* in the scope of a negative expression, are fine, but the b sentences are unacceptable.

(8a) Mary didn't find any coin.
(8b) *Mary found any coin.

(9a) No one ever squared the circle.
(9b) *Somebody ever squared the circle.

In addition to NPIs, we find a class of positive polarity items (PPIs). Positive polarity items typically occur in non-negative contexts. Just like NPIs, they belong to various syntactic categories. Examples of PPIs are quantifiers like *each* and *some*, factives like *be delighted that*, adverbs like *already*, and a rich variety of other expressions. The following examples show that PPIs shun negation:

(10a) Harry is already serving breakfast.
(10b) *Harry is not already serving breakfast

(11a) Everybody inspected each package.
(11b) *Nobody inspected each package.

Contexts that license NPIs however, need not contain overt negative elements. Thus negative polarity elements may be allowed in, for example, conditionals and *before*-clauses.

(12a) If you find any clue, you should report it to the police.
(12b) Mary left before John* already/even arrived.

In addition, some types of contexts only allow certain subclasses of polarity items. The central problem is thus to give a general characterization to the classes of contexts that license NPIs and PPIs and to relate different subclasses of polarity elements to the contexts that license them. On the question of why natural language contains such items and in view of what semantic properties makes them they behave as they

do, there is no agreement whatsoever. Though most authors assume that there is a general mechanism that governs all such items, they also assume that positive or negative polarity is at least in part a conventional feature that is given in the lexicon.

Klima (1964) called contexts that license NPIs, affective contexts. Affective contexts in Klima's sense are contexts that are either explicitly negative or contain an underlying negative element NEG. Related views are put forward by Baker (1970) and Linebarger (1980), who claim that NPIs are licensed by negative contexts but the negative element need not surface. Baker requires that the licensing context be either negative or entail a negative sentence. Linebarger states that a NPI may be licensed by an overt negative element or a negative implicature. Ladusaw (1979) was the first to propose a semantic characterization of negative context as a NPI licenser. According to Ladusaw, an expression acts as a trigger for NPIs if it denotes a downward entailing function. The central notion is downward entailment or downward monotonicity. The definition runs as follows:

> A function is downward entailing (monotone decreasing, downward monotonic) iff for all X and Y: if $X \subseteq Y$, then $f(Y) \subseteq f(X)$.

We can test for downward monotonicity by checking whether a context validates inferences from sets to subsets. Given that $\|\textit{chickpeas}\| \subseteq \|\textit{peas}\|$, the inference from (13a) to (13b) holds:

(13a) Mary doesn't eat peas.
(13b) Mary doesn't eat chickpeas.

And this predicts that (14a), where we find the NPI *any* in a downward entailing environment, is fine, though (14b) is unacceptable.

(14a) Mary doesn't eat any peas.
(14b) *Mary does eat any peas.

The converse property is upward entailment or upward monotonicity.

> A function f is upward entailing (upward monotonic) iff for all X and Y: if $X \subseteq Y$, then $f(X) \subseteq f(Y)$.

The inference from *Some Texans eat chickpeas* to *Some Texans eat peas* is valid, which shows that *Some Texans* is upward entailing.

Most authors agree that Ladusaw's generalization is basically right when taken as a necessary condition (e.g., Van der Wouden). In order to license an NPI, the context should have the property of downward monotonicity. Zwarts (1986), Hoeksema (1983), and van der Wouden (1997) show that the issue is more complicated, however. Not all NPIs are licensed in all downward monotonic contexts. As a consequence, they distinguish between weak and strong NPIs (Zwarts) or between weak, medium, and strong ones (Van der Wouden). Weak NPIs conform to Ladusaw's generalization, NPIs of medium strength and strong ones require contexts that satisfy additional algebraic properties. The picture that arises from this work is that polarity licensing of both NPIs and PPIs is not a homogeneous phenomenon.

There is an additional complication. According to the characterization given above, putting a PPI in a negative context yields ungrammaticality. However, such constructions often allow for a special interpretation that suggests that the corresponding non-negative sentence has been uttered before. Seuren (1985) calls this the 'echo' effect and takes it as an argument for the existence of a special presupposition-canceling negation operator. For Horn (1985, 1989), it is a diagnostic for a special use of negation he calls metalinguistic. Thus (15) is acceptable as a reaction to the utterance of *Mary is still in Paris*.

(15) Mary is NOT still in Paris. She never intended to be there and went to London instead.

It is implausible, though, that this phenomenon has anything to do with the formal properties of negation or negative context. We observe the same effect when NPIs are put in uncontroversially positive contexts.

(16) It DOES matter that my bunny is ill.

We return to the phenomenon of polarity reversal at the end of the last section.

Negation Versus Denial

The negation of a sentence is sometimes called its denial. It is, however, important to strictly separate the concepts of denial and negation. The concept of denial belongs to speech act theory. In this respect, denials are on a par with assertions. And, in contrast to negation, denials – just like assertions – should not be characterized in terms of truth and falsity but in functional terms. The primary function of assertions is to introduce new information, that is information that is not already taken for granted by the participants in a discourse. Denials differ in this respect. Their essential function is to object to information that has already been introduced before or is in some sense taken for granted. In doing so, a denial will have the effect of removing information from the discourse record. Despite being overtly negative, (17a) and (17b) will, if processed as the first sentence of a discourse, not be interpreted as denials but as assertions of negative sentences.

(17a) Mary is unhappy/not happy.
(17b) It does not matter that Mary read your letters.

Note, moreover, that a denial need not contain a negative morpheme. If uttered as a reaction to (17a) or (17b), B-b and B-c below will not be interpreted as assertions but as denials of the utterances they object to. The utterance by means of which the denial is performed may thus be of a negative or positive form. This shows that the concept of denial is logically independent of the concept of negation.

The difference in status of the concepts of denial and negation gave rise to a view according to which denials can be semantically characterized in terms of assertion and negation. Following Frege–Austin, Searle, and Dummett claimed that denials can be semantically analyzed as assertions of negative sentences. Further pragmatic effects that distinguish denials from assertoric utterances must be accounted for independently. Frege (1918: 149; Geach 1997: 40) – states: "People speak of affirmative and negative judgments; even Kant does so [...] For logic at any rate such a distinction is wholly unnecessary; its grounds must be sought outside logic." A linguist like Givón (1978) implicitly adopts the view that negation in language should be analyzed as a logical sign, which operates on sentences, but points out that denials have, in addition to their logical aspect, a pragmatic function that should be treated independently. Thus, though denials should logically be treated as negations of positive sentences, they constitute a different speech act from assertions. "While the latter are used to convey new information on the presumption of ignorance of the hearer, negatives are used to correct misguided belief on the assumption of the hearer's error." (Givón, 1978).

However, Frege also points out that it is not easy to make sense of the interpretation of denials as negative statements. "It is by no means easy to state what is a negative judgment (thought). Consider the sentences 'Christ is immortal', 'Christ lives for ever', 'Christ is not immortal', 'Christ does not live for ever'. Now which of the thoughts here is affirmative, which negative?[n] (Frege, 1918: 150; Geach 1977: 41). The central problem is that a treatment of the negation sign as a sign of denial forces us to introduce a further operator to account for negatory or denial force, in addition to the negation operator. Clearly, no operator that would go or fuse with Frege's assertion sign can be given a sensible interpretation in an embedded environment. Though an interpretation could be given to such an operator for simple sentences in an unembedded environment, it precludes the possibility of using this very same sentence as the antecedent of a conditional sentence. In this context, the sentence cannot have denial of negatory force. Fregean force always goes with full sentences and does not contribute to the proposition expressed. Thus in embedded environments, negation can only be interpreted as an ordinary functional expression, reversing the truth value of the proposition expressed. However, the introduction of some kind of denial operator having the same role as assertion would force us to recognize two ways of judging and accordingly two negative operators of a different status, one as some kind of speech act device, the other as a semantic operator reversing the truth value of the proposition expressed. Consequently, we should separate force from content, thus ending up with a theory that is preferable for being both conceptually and formally simpler.

Metalinguistic Negation

Horn (1985, 1989) drew attention to the fact that an utterance may not just be rejected in view of falsity of the propositional content, but that denials may instead apply to a variety of information, comprising presuppositions, various types of implicatures and connotations related to style and register. He points out that denials can be used to reject an utterance of a previous speaker for whatever reason. And equating the notions of denial and negation, he made a distinction between the well-known truth-functional operator and a non-truth-functional metalinguistic device. On this view, standard truth-functional negation is found in negative assertions and propositional denials. His metalinguistic device applies to presuppositional inferences, implicatures, and connotations of style and register. He labeled this device 'metalinguistic negation' and characterized it as follows: "I am claiming [...] for negation [...] a use distinction: it can be a descriptive truth-functional operator, taking a proposition p into a proposition $\neg p$, or a metalinguistic operator which can be glossed 'I object to u', where u is crucially a linguistic utterance rather than an abstract proposition" (Horn, 1985: 136). The relevant examples can be classified in the following categories:

A Assertions of negative sentences:
- (A-a) Mary is unhappy.
- (A-b) Mary is not happy.
- (A-c) It does not matter that Mary read your letters.

B Propositional denials:
- (B-a) Mary is NOT happy (as a reaction to the utterance of 'Mary is happy').
- (B-b) Mary IS happy (as a reaction to the utterance of A-a or A-b).
- (B-c) It DOES matter that Mary read my letters.

C Presuppositional denials:
- (C-a) The king of France is NOT bald – France does not have a king.
- (C-b) Virginia CANNOT know that the earth is flat.
- (C-c) John DIDN'T stop smoking – he never smoked.

D Implicature denials:
- (D-a) It is not POSSIBLE, it is NECESSARY that the church is right.
- (D-b) That haggis is not GOOD, it is EXCELLENT.
- (D-c) That was not a LADY I kissed last night – it was my WIFE.

E A variety of connotations (conventional implicature, style, register)
- (E-a) That is not a STEED – it's a HORSE.
- (E-b) Grandma didn't KICK THE BUCKET – she passed away.
- (E-c) He didn't call the POLICE, he called the POLICE.

Abstracting from their discourse function and focusing on truth conditional content, we may first note that Frege's strategy of analyzing the denial B-a as an assertion of a positive sentence works as far as truth conditional content goes. Assuming double negation in their underlying form, B-b and B-c can also be analyzed in the Fregean way. The presuppositional denials under C have historically either been handled by means of some nonstandard logic (thus postulating an ambiguity in the negation operator), or by an appeal to the Russellian notion of scope (see the first section above). More recent accounts that are formulated in a dynamic framework achieve a similar effect by invoking the notion of local accommodation. Though such theories take it that presuppositions normally escape from the scope of negation and other embedding operators, they introduce a special mechanism that forces presuppositional information – under specified conditions (e.g., threatening inconsistency) – to remain *in situ*, i.e., the place where they were triggered, and thus keep them within the scope of the embedding operator (Heim, 1983; Van der Sandt, 1992). The examples under D and E are problematic for any purely logical account. Their standard translations amount to plain contradiction, which led authors to call for some non-truth-functional analysis or else a nonliteral reinterpretation in view of a violation of Gricean maxims.

Horn treats categories C–E as metalinguistic uses of negation. The following diagnostics act as a kind of litmus test:

- Metalinguistic negation requires wide scope, thereby blocking lexical incorporation.
- Such sentences exhibit a rising intonation contour (fall-rise) pending further clarification, thereby stressing the offensive item or else triggering contrastive stress on the negative morpheme.
- Metalinguistic negation reverses the polarity of the sentence.

Example (18) illustrates the first diagnostic. In contrast to example D-a, it amounts to a straightforward contradiction:

(18) It is impossible, it is necessary that the church is right.

Note, moreover, that the same holds for example D-a if we destress the offensive item *possible*. Sentences (15) and (16) show that – contrary to received wisdom – negative denials accept PPIs, while positive denials allow NPIs.

Van der Sandt (1991, 2003) stressed that in view of their function, denials should be interpreted in context. They are not incremental in the sense assertions are, nor can they naturally occur in isolation. They take up or 'echo' a previous utterance; and since utterances convey information of various kinds (comprising presuppositions, implicatures, and further connotations), the interpretation of a denial may be sensitive to all the information that is invoked by the utterance they object to. Just as a speaker, when uttering any of the B sentences, objects to the truth-conditional content of a previously uttered sentence, he objects in the C cases to the presuppositions carried by a previous utterance, in the D cases to implicatures invoked, and in the E cases to offensive connotations of style and register a previous speaker may have conveyed with a corresponding non-negative utterance. Consider (19b), which is typically a reaction to (19a)

(19a) It is possible that the church is right.
(19b) It is not POSSIBLE, it is necessary that the church is right.

The utterance of (19a) invokes the implicature that it is not necessary that the church is right. By denying this utterance by means of (19b), the second speaker does not just react to the propositional content but to all the information conveyed by (19a). This information comprises the (scalar) implicature that it is not necessary that the church is right. Thus, if we take the negation in (19b) to apply to the full informative content of the first utterance, this yields an interpretation that can be paraphrased as (20):

(20) $\neg(\Diamond \text{ the_church_is_right} \wedge \neg \Box \text{ the_church_is_right}) \wedge \Box \text{ the_church_is_right}$

This simply conveys that it is necessary that the church is right and rejects all information conveyed by the previous utterance. The formal account is implemented in a nonincremental theory of discourse processing.

While Horn subsumes only presuppositional denials, implicature denials and the style and register cases under his notion of metalinguistic negation, Van der Sandt takes the phenomenon to be fully independent of the notion of negation and proposes an explanation of both the Horn cases and propositional denials based on the discourse properties of denial. Geurts (1998) objects to both views. According to him, denial or metalinguistic negation is not a homogeneous phenomenon. Instead he claims that a different semantic mechanism is operative in each of the cases B–E. His account divorces metalinguistic negations from the discourse characteristics of denial. Propositional denials are simply assertions of negative sentences. Presuppositional denials are handled by the mechanism of local accommodation. For the last two categories, Geurts assumes that the negative morpheme operates on a different level. For implicature denials, he invokes the notion of semantic polysemy. Crucially, he maintains that a scalar like *possible* may either have an *at least* or an exhaustive sense (i.e., *possible and not necessary*). Example (19a) selects the *at least* interpretation and here the exhaustive interpretation comes about by way of conversational implicature. In the denial (19b), the exhaustive sense is selected immediately. Only the style and register and pronunciation cases are metalinguistic in that they make reference to linguistic objects. Example E-b typically corrects the pronunciation of *police*. In this context, the phrase POlice corrects pronunciation, and here this phrase may be constructed as 'the body whose name is pronounced "POlice".'

Returning to the second section of this article, I conclude with a remark on polarity reversal. On the account that strictly distinguishes between the use of a (negative) sentence to convey new information and its use as a denial, polarity reversal falls out as a consequence of the discourse function of denial.

Consider first the unmarked (21a) and (21b):

(21a) It does not matter that Mary has read my letters.
(21b) Harry did not pick any of the flowers.

A denial interpretation of either of these sentences would require that the corresponding non-negative sentence has been uttered just before (or is at least 'in the air'). Note that their non-negated counterparts would contain a negative polarity element in a non-negative context and thus be ungrammatical. This forces the regular assertoric interpretation. But (16), which does contain an NPI in a non-negative context, can very well be used to echo a negative and thus grammatical utterance. An analogous explanation can be given for negative sentences containing PPIs. Since affirmative sentences containing PPIs require a non-negative context, their negated counterparts cannot be interpreted as isolated assertions. But they can very well be interpreted as the denial of a previous utterance, which being positive, is fully grammatical. Sentence (15) illustrates this.

Nenets

F Ackerman, University of California, San Diego, CA, USA
T Salminen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Nenets is a subbranch of the Samoyed branch of the Uralic family comprising two closely related but distinct languages, Forest Nenets (FN) and Tundra Nenets (TN). Tundra Nenets is spoken by nearly 30 000 people across the vast tundra zone of Arctic Russia and northwestern Siberia, while Forest Nenets has perhaps 1500 speakers along the Pur, Agan, Lyamin, and Nadym river basins in northwestern Siberia. A clear majority of the speakers are proficient in Russian, and in the European part of the Tundra Nenets territory in particular, the native language is in these days rarely transmitted to younger generations. In addition to Russian, Tundra Nenets has had contacts especially with Komi and Northern Khanty, and Forest Nenets has been greatly influenced by Eastern Khanty.

Besides Nenets, the Samoyed branch includes Nganasan, Enets (Forest Enets and Tundra Enets), Yurats, Selkup (Northern Selkup, Central Selkup, and Southern Selkup), Kamas, and Mator; of these, Yurats, Kamas, and Mator are extinct, the Enets languages as well as Central Selkup and Southern Selkup are critically endangered; Nganasan is still spoken by approximately 500 people and Northern Selkup by 1500. Samoyed is the easternmost branch of the Uralic family; the other branches are Khanty, Mansi, Hungarian, Permian, Mari, Mordvin, Finnic, and Saami.

The Nenets languages are synthetic, agglutinating with some fusion and, in Forest Nenets, metaphony, morphophonologically complex, suffixing and predominantly verb-final.

The vowel system of Tundra Nenets in the first syllable includes nine vowels differing in both quality and quantity (one short vowel marked with *ø* in phonological transcription, five basic vowels, *i e a o u*, a mixed [diphthongoid] vowel *æ*, and two long vowels, *í ú*; in unstressed syllables, a schwa, °, typically realized as extra lengthening of the preceding segment, occurs in addition to the five basic vowels. The Forest Nenets vowel system has been restructured after the Eastern Khanty model and consists of stressed syllables of six long vowels, *i e ä a o u*, and four short vowels, *î ã â û* (corresponding to *i ä a u*); in unstressed syllables, only a schwa ° and *i a u* are possible. The stress is not contrastive but falls on nonfinal odd or pre- and postschwa syllables. A feature affecting both consonants and vowels is palatalization: the traditional formulation is that vowels have back vs. front allophones after nonpalatalized vs. palatalized consonants, but palatality (marked with *y* between a consonant and vowel in phonological transcription) can also be understood as a suprasegmental feature with a CV sequence under its scope. The consonant system of Tundra Nenets consists of 26 units (up to 31 in dialects); in Forest Nenets there are 24 consonants. Both systems include a velar nasal (*ng*) and a velar fricative (*x*); in Forest Nenets, vibrants have changed to fricolaterals (*lh*) under the Eastern Khanty influence; in Tundra Nenets, there are affricates (*c*) that have developed from consonant clusters still retained in Forest Nenets; both languages have a glottal stop marked with *q* or, in Tundra Nenets, *h* in case it has nasal sandhi alternants. The above figures include palatalized consonants, which in Tundra Nenets are only contrastive in the labial and dental series, while in Forest Nenets, there are palatalized velars as well. An old phonotactic peculiarity of Nenets is the lack

Nenets is a subbranch of the Samoyed branch of the Uralic family comprising two closely related but distinct languages, Forest Nenets (FN) and Tundra Nenets (TN). Tundra Nenets is spoken by nearly 30 000 people across the vast tundra zone of Arctic Russia and northwestern Siberia, while Forest Nenets has perhaps 1500 speakers along the Pur, Agan, Lyamin, and Nadym river basins in northwestern Siberia. A clear majority of the speakers are proficient in Russian, and in the European part of the Tundra Nenets territory in particular, the native language is in these days rarely transmitted to younger generations. In addition to Russian, Tundra Nenets has had contacts especially with Komi and Northern Khanty, and Forest Nenets has been greatly influenced by Eastern Khanty.

Besides Nenets, the Samoyed branch includes Nganasan, Enets (Forest Enets and Tundra Enets), Yurats, Selkup (Northern Selkup, Central Selkup, and Southern Selkup), Kamas, and Mator; of these, Yurats, Kamas, and Mator are extinct, the Enets languages as well as Central Selkup and Southern Selkup are critically endangered; Nganasan is still spoken by approximately 500 people and Northern Selkup by 1500. Samoyed is the easternmost branch of the Uralic family; the other branches are Khanty, Mansi, Hungarian, Permian, Mari, Mordvin, Finnic, and Saami.

The Nenets languages are synthetic, agglutinating with some fusion and, in Forest Nenets, metaphony, morphophonologically complex, suffixing and predominantly verb-final.

The vowel system of Tundra Nenets in the first syllable includes nine vowels differing in both quality and quantity (one short vowel marked with *ø* in phonological transcription, five basic vowels, *i e a o u*, a mixed [diphthongoid] vowel *æ*, and two long vowels, *í ú*; in unstressed syllables, a schwa, °, typically realized as extra lengthening of the preceding segment, occurs in addition to the five basic vowels. The Forest Nenets vowel system has been restructured after the Eastern Khanty model and consists of stressed syllables of six long vowels, *i e ä a o u*, and four short vowels, *î ã â û* (corresponding to *i ä a u*); in unstressed syllables, only a schwa ° and *i a u* are possible. The stress is not contrastive but falls on nonfinal odd or pre- and postschwa syllables. A feature affecting both consonants and vowels is palatalization: the traditional formulation is that vowels have back vs. front allophones after nonpalatalized vs. palatalized consonants, but palatality (marked with *y* between a consonant and vowel in phonological transcription) can also be understood as a suprasegmental feature with a CV sequence under its scope. The consonant system of Tundra Nenets consists of 26 units (up to 31 in dialects); in Forest Nenets there are 24 consonants. Both systems include a velar nasal (*ng*) and a velar fricative (*x*); in Forest Nenets, vibrants have changed to fricolaterals (*lh*) under the Eastern Khanty influence; in Tundra Nenets, there are affricates (*c*) that have developed from consonant clusters still retained in Forest Nenets; both languages have a glottal stop marked with *q* or, in Tundra Nenets, *h* in case it has nasal sandhi alternants. The above figures include palatalized consonants, which in Tundra Nenets are only contrastive in the labial and dental series, while in Forest Nenets, there are palatalized velars as well. An old phonotactic peculiarity of Nenets is the lack

of initial vowels: this is now relaxed in most varieties, but in the Central dialects of Tundra Nenets the principle is still fully alive and is even reflected in recent Russian loanwords such as *ngarmiya* 'army.' In Tundra Nenets, there is a sandhi system affecting both the final consonant of the preceding word and the initial consonant of the following one, for instance, *nyeh xøn°* 'woman's sledge' is transformed to *nyeng_køn°*, *pyíq xøn°* 'sledge for wood' to *pyí_køn°*, and *ngarka to* 'big lake' to *ngarka_do* by sandhi.

Nouns distinguish seven cases: nominative, accusative, and genitive are the grammatical cases that in their basic functions denote subject, object, and possessor; dative, locative, ablative, and prosecutive ('through, along, by') constitute the local cases. There are three numbers, singular, dual, and plural, but there is a gap in the nominal paradigm in that the local cases do not combine with the dual number, the respective meanings being expressed by postpositional phrases. The inflection of personal pronouns follows a distinct pattern, and their local cases are also replaced with forms of postpositions. Besides absolute declension, the nominal inflection includes possessive as well as predestinative ('for') forms, e.g., FN *wyîq* 'water': *wyîqj°* 'my water': *wyîqtâj°* 'water for me.' The postpositions are typically inflected in local cases and have possessive forms as well, e.g., FN ablative *ngîlh°tâj°* 'from under me' or prosecutive *pumnantung* 'along their tracks.' In predicative position, nouns agree with the subject employing the same personal suffixes (but not showing the other inflectional peculiarities) as intransitive verbs, e.g., TN *lúca* 'Russian': *lúcad°m* 'I am a Russian.'

Verbs have numerous grammatical categories, covering person, number, tense, and mood. The number of moods is large, in Tundra Nenets up to 18, making it possible to express various levels of probability and necessity morphologically; the imperative and optative moods employ sets of personal suffixes different from other moods. Perfective vs. imperfective aspect is an inherent feature of a verb, and aspectual pairs are created through derivational morphology. The tense is expressed by two distinct systems: first, there is an opposition between unmarked basic tense and suffixally marked future and habitive tenses; second, there is unmarked aorist vs. preterite marked by a suffix that morphotactically follows the personal suffix; it is possible to combine the two tense systems, e.g., TN *xada-* 'kill': aorist *xadaøw°* 'I killed it (just now)': preterite *xada°wøsy°* 'I killed it (earlier)': future aorist *xadangkuw°* 'I am going to kill it': future preterite *xadangkuwøsy°* 'I was going to kill it.' As seen from the examples, the basic aorist refers to immediate past in case of perfective verbs such as 'kill,' whereas the aorist of imperfective verbs simply expresses present, e.g., *nyoda-* 'follow': *nyodaøw°* 'I am following it.' A specific grammatical category in Nenets is known as conjugation: it covers the opposition between subjective forms used when the object is focused and objective forms referring to previously known or omitted objects, e.g., TN *tim xadaød°m* 'I killed a/the reindeer (and not another animal)' vs. *tim xadaøw°* 'I killed the reindeer (instead of doing something else to it)'; in the objective conjugation, the number of the object is expressed morphologically, e.g., *xadangax°yun°* 'I killed them (two)' vs. *xadeyøn°* 'I killed them (several)'; furthermore, there are reflexive forms that either contrast with forms with a transitive meaning, e.g., *tonta-* 'cover': objective *tonta°da* '(s)he covered it': reflexive *tontey°q* 'it got covered,' or constitute the only finite forms of a lexical verb, typically expressing sudden movement or change in state. The personal suffixes cannot generally be attached directly to the verbal stem, but they trigger a complex system of morphological substems.

There is a wide range of nonfinite verbal forms in Nenets, with an important function in embedded clauses (either independently or within postpositional phrases, often with switch-reference, whereby a nonfinite verb is marked differently depending on whether its subject is the same as, or differs from, that of the finite verb), as there are no conjunctions or relative pronouns. Negation is expressed by a negative auxiliary verb incorporating all categories of verbal inflection followed by a specific connegative form of a lexical verb, e.g., TN *nyíx°yun° xadaq* 'I did not kill them (two)'; since the nominal paradigm lacks a connegative, negative nominal predicates must incorporate a copula, e.g., TN *lúcad°m nyíd°m ngaq* 'I am not a Russian.'

Within the basic SOV word order of a transitive sentence, the adverbial phrases are typically placed as Time S Place/Recipient O Manner V, but any focused element can occur preverbally, and even postverbal constituents are possible in case of two morphologically or functionally similar phrases, e.g., FN *ngopk°na myatuqngaj° mâj° myaqk°naj°* 'we (two) live together in our tent,' where both *ngopk°na* 'together' and *mâj° myaqk°naj°* 'in our tent' are in the locative case. In imperative sentences, typically without an overt subject, the nominal object is in the nominative instead of the accusative. The personal pronouns, by contrast, employ their accusative forms even in imperative sentences, while in possessive phrases with a morphologically marked possessed noun they appear, if not omitted, in the nominative rather than in the genitive. Agreement within a

nominal phrase is possible in number when the non-singularity of the noun is more definite, and in relative clauses possessive agreement also occurs, e.g., TN *metyida wadyida* 'note the words he uses', cf. *meta* imperfective participle of 'use,' *wada* 'word.'

Both Nenets languages are endangered, but there are major differences between localities in language use. Tundra Nenets has a literary language deriving from the 1930s used in semiregular book printing and having a limited presence in schools and the press, while Forest Nenets remained unwritten until the 1990s, when a primer and a school dictionary appeared. In the areas where the languages remain vigorous, oral literature, including tales, stories, and riddles as well as epic, lyric, and personal songs, is also flourishing (Castrén and Lehtisalo, 1940; Lehtisalo, 1947; Kupriyanova, 1965; Tereshchenko, 1990; Niemi, 1998). The traditional way of life based on reindeer husbandry or fishing (Khomich, 1995) continues to be appreciated by many Nenets as long as oil and gas excavations do not entirely destroy their lands and the authorities do not force them to relocate (Golovnev and Osherenko, 1999).

For a small indigenous language, Tundra Nenets is reasonably well studied, especially with regard to its phonology and morphology (Castrén, 1854; Tereshchenko 1947, 1956; Décsy, 1966; Janhunen, 1986; Salminen, 1997, 1998a) and lexicon (Pyrerka and Tereshchenko, 1948; Lehtisalo, 1956 [covering both Nenets languages]; Tereshchenko, 1965), while there is only one monograph devoted to the syntax of the Samoyed languages in general (Tereshchenko, 1973). This article is mainly based on Salminen (1998b) as well as more recent field studies funded by the Endangered Languages Documentation Programme. Forest Nenets has been studied much less extensively than Tundra Nenets, with a couple of basic grammatical treatments published (Verbov, 1973; Sammallahti, 1974).

Neo-Gricean Pragmatics

Y Huang, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

In 1967, H. P. Grice delivered his Williams James Lectures at Harvard. In these lectures, Grice presented a panorama of his thinking on meaning and communication – what he called his "tottering steps" (Grice, 1989) toward a systematic, philosophically inspired pragmatic theory of language use, which has since come to be known as 'Gricean pragmatic theory.' Since its inception, Gricean pragmatics has revolutionized pragmatic theorizing and has to date remained one of the cornerstones of contemporary thinking in linguistic pragmatics and the philosophy of language. This article undertakes to present and assess a neo-Gricean pragmatic theory of conversational implicature, focusing on the bipartite model developed by Laurence Horn and the tripartite model advanced by Stephen Levinson (*see* **Implicature; Maxims and Flouting**).

The Hornian System

Horn (1984, 1989, 2004) developed a bipartite model. In Horn's view, all of Grice's maxims (except the maxim of quality) can be replaced with two fundamental and antithetical principles: the quantity (Q-) and relation (R-) principles.

(1) Horn's Q- and R-principles:
  (a) The Q-principle:
    Make your contribution sufficient.
    Say as much as you can (given R).
  (b) The R-principle:
    Make your contribution necessary.
    Say no more than you must (given Q).

In terms of information structure, the Q-principle is a lower bounding pragmatic principle that may be (and characteristically is) exploited to yield upper bounding conversational implicatures: a speaker, in saying '. . . *p* . . . ,' conversationally implicates that (for all he or she knows) '. . . at most *p* . . .' (*see* **Implicature**). The *locus classicus* here is those conversational implicatures that arise from a prototype Horn-scale. Prototype Horn-scales are defined in (2) (see Levinson, 1987, 2000):

(2) Prototype Horn-scales:
  For <*S*, *W*> to form a Horn-scale:
  (a) A(*S*) entails A(*W*) for some arbitrary sentence frame A.
  (b) *S* and *W* are equally lexicalized, of the same word class, and from the same register.
  (c) *S* and *W* are 'about' the same semantic relation, or from the same semantic field.

An example of Q-implicature is given in (3) (the symbol '< >' represents 'Q-scale'; '+>' represents 'conversationally implicates'):

(3) <all, some>
  Some of his friends took a taxi to the station.
  +> Not all of his friends took a taxi to the station.

On the other hand, the counterbalancing R-principle is an upper bounding pragmatic law that may be (and systematically is) exploited to engender low-bounding conversational implicatures: a speaker, in saying '. . . *p* . . . ,' conversationally implicates that (for all he or she knows) '. . . more than *p* . . .' (Atlas and Levinson, 1981). This is illustrated in (4):

(4) Have you got a watch?
  +> If you have got a watch and know the time, please tell me what time it is.

Viewing the Q- and R-principles as instantiations of Zipfian economy (Zipf, 1949), Horn explicitly identified the Q-principle ("a hearer-oriented economy for the maximization of informational content") with Zipf's 'auditor's economy' (the force of diversification), and identified the R-principle ("a speaker-oriented economy for the minimization of linguistic form") with Zipf's 'speaker's economy' (the force of unification). Furthermore, Horn argued that the whole Gricean mechanism for pragmatic inference can be largely derived from the dialectic interaction (in the classical Hegelian sense) between the Q- and R-principles in the following way:

(5) Horn's division of pragmatic labor: The use of a marked (relatively complex and/or prolix) expression when a corresponding unmarked (simpler, less 'effortful') alternate expression is available tends to be interpreted as conveying a marked message (one that the unmarked alternative would not or could not have conveyed).

In effect, what (5) says is this: the R-principle generally takes precedence until the use of a contrastive linguistic form induces a Q-implicature to signal the nonapplicability of the pertinent R-implicature (for further discussion, see Huang, 1991, 1994, 2000, 2003, 2004a,b, 2005).

The Levinsonian System

Horn's proposal to reduce Grice's maxims to the Q- and R-principles was called into question by Levinson (1987, 1991, 2000). In Levinson's view, Horn failed to draw a distinction between what Levinson called semantic minimization ("semantically general expressions are preferred to semantically specific ones") and expression minimization ("'shorter' expressions are preferred to 'longer' ones"). Consequently, inconsistency arises with Horn's use of the Q- and R-principles. For example, in Horn's division of pragmatic labor (see (5)), the Q-principle operates primarily in terms of units of speech production, whereas elsewhere, in Horn-scales (see (2)), for instance, it operates primarily in terms of semantic informativeness.

Considerations along these lines led Levinson to argue for a clear separation between pragmatic principles governing an utterance's surface form and pragmatic principles governing its informational content. He proposed that the original Gricean program (the maxim of quality apart) be reduced to three neo-Gricean pragmatic principles, or what he dubbed the quantity (Q-), informativeness (I-), and manner (M-) principles. Each of the three principles has two sides: a speaker's maxim, which specifies what the principle enjoins the speaker to say, versus a recipient's corollary, which dictates what this allows the addressee to infer:

(6) Levinson's Q-principle (simplified):
Speaker's maxim: Do not say less than is required (bearing I in mind).
Recipient's corollary: What is not said is not the case.

The basic idea of the metalinguistic Q-principle is that the use of an expression (especially a semantically weaker one) in a set of contrastive semantic alternates (such as a Horn-scale) Q-implicates the negation of the interpretation associated with the use of another expression (especially a semantically stronger one) in the same set. In other words, as already mentioned, the effect of this inference strategy is to give rise to an upper bounding conversational implicature. Seen the other way round, from the absence of an informationally stronger expression, it is inferred that the interpretation associated with the use of that expression does not hold. Hence, the Q-principle is essentially negative in nature.

Three types of Q-implicatures can then be identified: $Q_{\text{-scalar}}$ implicatures, $Q_{\text{-clausal}}$ implicatures, and $Q_{\text{-alternate}}$ implicatures. The $Q_{\text{-scalar}}$ implicatures are derived from prototype Horn-scales. They were illustrated in (3) (recall that '+>' represents 'conversationally implicate') and are shown schematically in (7):

(7) $Q_{\text{-scalar}}$: <x, y>
y +> $Q_{\text{-scalar}} \sim$ x

$Q_{\text{-clausal}}$ implicatures are inferences of epistemic uncertainty (Gazdar, 1979). They are shown schematically in (8) and are exemplified in (9):

(8) $q_{-\text{clausal}}$: $< x(p), y(p) >$
$y(p) +> q_{-\text{clausal}}\ p, \sim p$

(9) <(since *p*, then *q*), (if *p*, then *q*)>
If you want to sell more, you should reduce your prices.
+> You may want to sell more, or you may not; perhaps you should reduce your prices, or perhaps you should not.

$Q_{\text{-alternate}}$ implicatures come from a nonentailment semantic contrast set (Harnish, 1976; Horn, 1989; Hirschberg, 1991; Levinson, 2000). Roughly, there are two subtypes here. In the first, the expressions in the set are informationally ranked, as in (10). Following Huang (2005), let us call this subtype 'Q-ordered' alternate implicatures. By contrast, in the second subtype, the expressions in the set are of equal semantic strength, as in (11). Let us term this subtype 'Q-unordered' alternate implicatures:

(10) <marry, engage>
They've engaged.
+> They haven't got married.

(11) <dog, cat, hamster, Λ>
John has a dog.
+> He doesn't have a cat, a hamster, and Λ as well.

We come next to Levinson's I-principle:

(12) Levinson's I-principle (simplified):
Speaker's maxim: Do not say more than is required (bearing Q in mind).
Recipient's corollary: What is generally said is stereotypically and specifically exemplified.

Mirroring the effects of the Q-principle, the central tenet of the I-principle is that the use of a semantically general expression I-implicates a semantically specific interpretation. In other words, as already noted, the working of this inferential mechanism is to induce a lower bounding conversational implicature. More accurately, the conversational implicature engendered by the I-principle is one that accords best with the most stereotypical and explanatory expectation, given our real-world knowledge. This is depicted schematically in (12) (the '[ ]' here is intended to indicate an 'I-scale']:

(13) I-scale: [x, y]
$y +>_I x$

The class of I-implicature is heterogeneous, ranging from conjunction buttressing (as in (14)) through negative raising to interpretation of spatial terms, but I-implicatures do share a number of properties, notably: (a) they are more specific than the utterances that engender them, (b) unlike Q-implicatures, they are positive in nature, (c) they are characteristically guided by stereotypical assumptions, (d) they are nonmetalinguistic, in the sense that they make no reference to something that might have been said but was not (*see* **Metapragmatics**), and (e) unlike Q-implicatures, they normally cannot be canceled by metalinguistic negation (for an attempt to formalize the Q- and I-principles, see Blutner (1998)):

(14) *p* and *q* +> *p* and then *q*
+> *p* therefore *q*
+> *p* in order to cause *q*
John pressed the spring and the drawer opened.
+> John pressed the spring and then the drawer opened.
+> John pressed the spring and thereby caused the drawer to open.
+> John pressed the spring in order to make the drawer open.

We finally turn to Levinson's M-principle:

(15) Levinson's M-principle:
Speaker's maxim: Do not use a marked expression without reason.
Recipient's corollary: What is said in a marked way is not unmarked.

Unlike the Q- and I-principles, which operate primarily in terms of semantic informativeness, the metalinguistic M-principle operates primarily in terms of a set of alternates that contrast in form. The fundamental axiom on which this principle rests is that the use of a marked expression M-implicates the negation of the interpretation associated with the use of an alternative, unmarked expression in the same set. Putting it another way, from the use of a marked linguistic expression, it can be inferred that the stereotypical interpretation associated with the use of an alternative, unmarked linguistic expression does not obtain. This can be represented schematically as in (16) (the symbol '{ }' indicates an 'M-scale'):

(16) M-scale : {x, y}
$y +>_M \sim x$

An example of M-implicatures is given in (17b):

(17a) Mary went from the bathroom to the bedroom.
+> in the normal way

(17b) Mary ceased to be in the bathroom and came to be in the bedroom.
+> in an unusual way, e.g., in a magic show, Mary had been made to disappear by magic from the bathroom and reappear in the bedroom.

Given the preceding tripartite classification of neo-Gricean pragmatic principles, the question that arises next is how inconsistencies arising from these potentially conflicting inference apparatuses can be dealt with. According to Levinson (1991, 2000), they can be resolved by an ordered set of precedence, which encapsulates in part Horn's division of pragmatic labor, as previously discussed.

(18) Levinson's resolution schema for the interaction of the Q-, I-, and M-principles:
(a) Level of genus: Q > M > I.
(b) Level of species: e.g., $Q_{\text{-clausal}} > Q_{\text{-scalar}}$.

This is tantamount to saying that genuine Q-implicatures (whereby $Q_{\text{-clausal}}$ cancels rival $Q_{\text{-scalar}}$) takes precedence over inconsistent I-implicatures, but otherwise I-implicatures take precedence, until the use of a marked linguistic expression triggers a complementary M-implicature, leading to the negation of the applicability of the pertinent I-implicature

(for further discussion, see Levinson, 2000; Huang, 1991, 1994, 2000, 2003, 2004a,b, 2005).

Further Neo-Gricean Contributions

Building on the Gricean generalized versus particularized implicatures dichotomy, Levinson (1995, 2000) developed a theory of presumptive meaning. He proposed to add a third level – utterance-type meaning – to the two generally accepted levels of sentence-type meaning and utterance-token meaning. This third layer is the level of generalized, preferred, or default interpretation, which is not dependent on direct computations about speaker intentions, but rather on expectations about how language is characteristically used. Stated thus, a neo-Gricean pragmatic theory of conversational implicature is essentially a theory of presumptive meaning – pragmatic inference that is generalized, arises by default, and thus is presumed. Furthermore, on a classical Gricean account, the total signification of an utterance is divided into what is said and what is implicated. Simply put, what is said is generally taken to be mapped onto the truth-conditional content of an utterance. What is implicated is then defined in contrast to, and is calculated on the basis of, what is said (and in the case of M-implicatures, together with how what is said, is said). Seen in this light, what is said is supposed to provide the input to what is implicated.

To work out what is said, according to Grice (1989), it is required to (a) resolve reference, (b) fix deixis, and (c) disambiguate expressions. To these requirements, Levinson (2000) added (d) unpacking ellipsis, and (e) narrowing generalities. It turns out, however, that the determination of requirements (a)–(e) involves pragmatic inference of some kind. Put another way, there is 'pragmatic intrusion' of some sort, namely, the intrusion of pragmatically inferred content into truth-conditional content, involved in the working out of what is said. The question that arises next is what kind of pragmatic intrusion it is. Roughly, there are two positions. The first is that the pragmatic inference under consideration is of a special kind, which differs from conversational implicature. Within this camp, of particular interest are two lines of argument. According to Sperber and Wilson (1986), the pragmatic inference is an 'explicature' (*see* **Relevance Theory**). Another argument is due to Bach (1994), who proposed a third category of communicative content, intermediate between Grice's 'what is said' and 'what is implicated.' Bach dubs the vehicle of such a content 'impliciture,' since it is implicit in what is said. The second position is represented by Levinson (2000), who argued that these so-called explicatures/implicitures result from the same pragmatic apparatus that engenders what is implicated. Therefore, they are largely the same beast as conversational implicature. Consequently, this gives rise to a problem known as 'Grice's circle,' namely, how what is implicated can be defined in contrast to, and calculated on the basis of, what is said, given that what is said seems both to determine and to be determined by what is implicated (e.g., Huang, 1991). Levinson's (2000) proposal was to reject the 'received' view of the pragmatics–semantics interface, namely, the view that the output of semantics is the input to pragmatics, and even to allow implicatures to play a systematic role in 'pre'-semantics, i.e., in the derivation of the truth-conditional content of an utterance. These matters will continue to be debated (*see* **Pragmatics and Semantics; Maxims and Flouting; Principles and Rules**).

In recent years, the classical Gricean theory of conversational implicature has successfully and profitably been generalized to other core areas of linguistics. One such area is formal syntax, and the particular topic of inquiry is anaphora. Levinson (1987, 1991, 2000) and Huang (1991, 1994, 2000, 2004a) developed a (revised) neo-Gricean pragmatic theory of anaphora (*see* **Deixis and Anaphora: Pragmatic Approaches**). The theory has effected a radical simplification of formal syntax, especially as regards Chomsky's binding theory (*see* **Syntax-Pragmatics Interface: Overview; Pragmatics: Optimality Theory**) Finally, a number of neo-Gricean experimental works have appeared, putting various aspects of classical and neo-Gricean pragmatic theory to a test (for further discussion, see Huang, 2003, 2004b).

Neologisms

A Lehrer, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

New words frequently appear in English. Some words enter the language while others are used for a short time, or perhaps only once. During the last century, however, the rate of growth has accelerated. Neologisms draw on traditional word-formation devices, but some processes which were previously marginal have become common, for example, the new bound morpheme *-holic* as in the blend *workaholic*. Another process which has become productive is verb-headed compounds like *oil-paint*.

Neologisms Based on Common Word Formation Devices

One of the commonest word formation devices is compounding – combining two or more free morphemes. Compounds can be headed by any major lexical class, and all types are found in neologisms. A few examples are *jock talk* (N-N), *ripjob* 'negative publicity' (V-N), *dolphin-safe* (N-ADJ), *fail-safe* (V-ADJ), *red-hot* (ADJ-ADJ) *after-born* 'child born after the father's death' (P-ADJ), *over-quick* (P-ADV), and *off base* (P-N).

Traditional textbooks such as Marchand (1960), Selkirk (1982), Bauer (1983), and Spenser (1991) claim that verb-headed compounds are rare. The few existing ones are backformed by deletion of a suffix such as *-er* or *-ing* or formed by, for example, converting a compound noun into a verb. Examples are *sky-dive*, derived from *sky-diving*, and *carbon-copy*, which becomes a verb by being converted from a noun compound (Bauer, 1983: 208). The compound *self-destruct* is backformed from *self-destruction*. Although verb-headed compounds may have been rare in the past, this is no longer true. They occur so frequently in print and in spontaneous speech that it is reasonable to conclude that such compounds have become productive in recent years. In addition to the few listed in the works cited (*air-condition*, *baby-sit*, and *breast-feed*) are many other already conventional verb-headed compounds: *lip-read*, *gift wrap*, *copyread*, *custom-make*, *double-park*, *brain-wash*, *flight-test*, *test-drive*, *spot-check*, *window-shop*, *plea-bargain*, *stir-fry*, *chain-smoke*, *handpick*, *stage-manage*, *code-switch*, *guest-conduct*, *dry-clean*, *sun-dry*, *spot-weld*, *backpedal*, *channel-surf*, and *spell-correct*. Many verb-headed compounds are used in sports: *bounce-pass*, *pinch-hit*, *bucket-drive*, *speed-climb*, *jump-shoot*, *jump-pass*, and *kick-turn*. Many compounds are formed with the verb *hop*, as *in bed-hop*, *castle-hop*, *island-hop*, and with initial *self*:

Neoclassical Compounding

A Lüdeling, Institut für deutsche Sprache und Linguistik, Humboldt University, Berlin, Germany

Neoclassical word formation is word formation with elements of Greek or Latin origin. In the European languages neoclassical word formation is found 'next to' native word formation. In these languages neoclassical elements combine productively with each other (cf. *automobile, morphology, hydrophobic*) and with native elements (see below).

History and Scope of Neoclassical Word Formation

A neoclassical word or element is not simply any element that is etymologically Latin or Greek. Because Latin (and partly Greek) was the European lingua franca and the official language in many countries for many centuries, it is no wonder that many Latin and Greek elements found their way into the European languages. Elements that were borrowed early are often phonologically and morphologically assimilated and show no structural differences to native words (examples are German *Fenster* 'window' from Latin *fenestra,* which became trochaic and lost the full vowel in the last syllable or English *market* from Latin *mercatus*). Such elements behave in word formation just like native elements.

What we call neoclassical word formation, on the other hand, uses elements that are not totally assimilated. It became productive in the 17th and 18th centuries in many European languages, mainly because there was a movement away from Latin as a lingua franca to the vernacular languages. At the same time the evolution of sciences furthered the development of terminology that used and combined classical elements. Neoclassical words are not simple borrowings but are formed by new mechanisms that often differ from word formation with native stems. (This is a very rough picture; for a historical survey of the development and influence of Latin and Greek elements in some European languages see Munske and Kirkness, 1996, and histories of the morphology of each language, e.g., von Polenz, 1994, for German, Marchand, 1969, or Baugh and Cable, 2002, for English.) Because there are many elements, words, and mechanisms that are similar across different languages (sometimes called internationalisms), there are a number of common questions that need to be addressed in morphological theory. These concern the status of neoclassical elements, the nature of their combination and the question of their productivity.

The Status of Neoclassical Elements

Regarding the morphological status of neoclassical elements two questions must be addressed (a) How do neoclassical and native elements differ from each other? and (b) Are neoclassical elements like *hydr(o)-*, *psych(o)-* or *–morph/morph(o)-* stems or affixes?

As described earlier, the notion 'neoclassical' is not simply an etymological notion. First, speakers cannot be expected to have etymological knowledge. In addition, it is often difficult to determine the origin of a morphological element because many elements reach a language via other languages. Is an originally Latin element that reached English via German – and has perhaps undergone changes on its way – Germanic or classical (cf. Anshen *et al.*, 1986)? Therefore 'neoclassical' (or 'latinate' or 'learned') refers to structural properties of some elements that distinguish them from 'native' elements in the base language. These structural differences can be

a. Phonological: neoclassical affixes may attract or bear stress, cf. *cèremony – ceremònious*, *sincère – ìnsincere*, while Germanic affixes do not. Neoclassical words may have sounds that are not phonemes in the base language.
b. Morphological and morphophonological: neoclassical elements tend to combine mainly with other neoclassical elements (see following section) and affix ordering principles may be sensitive to the neoclassical-native distinction (Kiparsky, 1982; Aronoff and Fuhrhop, 2002).
c. Orthographic: neoclassical elements may contain graphemes (for example <ph> in *philosophy*) that are not part of the grapheme inventory of the base language.
d. Use: neoclassical elements are often used in 'higher' or 'learned' registers.

Lüdeling *et al.* (2002) show that these differences do not lead to clear-cut categories but rather have to be seen as constituting similarity classes. It seems clear, however, that in many languages the class of neoclassical elements is distinguishable (at least in many cases) from the class of native elements. Randall (1980) provides psycholinguistic evidence that speakers distinguish between native and neoclassical elements.

In a simple morphological model that distinguishes between affixes and stems, the status of many neoclassical elements is difficult to determine. Semantically, they behave like stems but often they appear only as bound forms. Examples are *psych(o)-*, *hydr(o)-*, *morph(o)-* or *-(o)phob*, *-(o)log-* (the modes of combination and the status of the 'linking element' *o* are taken up in the next section).

To mark this, neoclassical elements are sometimes called formatives, combining forms or confixes (see Donalies, 2000). Generative theorists have come to different conclusions concerning the status of these elements. Aronoff (1976), in his word-based approach, assumes that these elements have no status but occur only in complex words. Others, like Scalise (1986) or Selkirk (1982), argue that these elements are bound stems. Still others assume that these elements are affixes (Williams, 1981). In this view there would be words consisting only of affixes. Finally, Lüdeling *et al.* (2002) and Lüdeling and Schmid (2003) propose that the features bound and selecting should be used rather than the stem-affix distinction. The preceding described elements are then bound, nonselecting elements.

Another point that is often discussed in this area is the question whether some of the neoclassical elements should be seen as abbreviations or clipped forms rather than as full elements – an examples would be *gastro-* in *gastroguide* where *gastro-* stands for *gastronomy* (see Petropoulou and ten Hacken, 2002). It is clear that any analysis of these elements has implications for the classification of the morphological process that combines them.

The Status of Neoclassical Word Formation

Before discussing the theoretical status of neoclassical combination the different modes of combination need to be described.

Although details differ between languages, in general we have the 'bound stems' described earlier that combine with each other to *morpholog-, hydrophob, telephone*. This is sometimes called neoclassical compounding. Neoclassical compounds and neoclassical elements also sometimes combine with neoclassical affixes to *morphology, morphologist, hdrophobia,* or *hippopotomonstrosesquippedaliophobia* 'fear of long words' (the two *p*s are really used here). Although neoclassical elements tend to combine with other neoclassical elements, there are also patterns in which neoclassical elements combine with native elements. This seems unproblematic when the neoclassical element itself is a free element (cf. German *Flugnavigation* 'flight navigation'), but some authors assume that it is problematic to combine native elements with bound neoclassical elements – the results are sometimes called 'hybrid' formations (van Marle, 1985, states that such combinations aim at a 'special effect'). This is taken as one argument for the assumption that neoclassical word formation and native word formation form separate systems. The picture is not as simple as this, however. Although there are neoclassical elements that are quite specific in their selectional restrictions there are others that combine easily with native elements (Bauer, 1998; Booij, 2002; Lüdeling *et al.*, 2002; Lüdeling and Schmid, 2003). As an example consider the negation prefixes *un-* (Germanic) and *in-* (from Latin). Although it is in general true that *in-* (or one of its allomorphs) attaches only to classical words, it is not always true that *un*-attaches only to Germanic words, compare *uninteresting*, *unconscious* or the unclear situation in *undigestable/indigestable*.

Often, a 'linking element' (mostly *o* but sometimes other vowels) is added between two elements: *morph-o-logy*. Does this 'linker' belong to the first or to the second element? In contrast to 'linking elements' in many Germanic compounds, which are usually assumed to belong to the nonhead of the compound, here we seem to have patterns in which each element requires an *o* (and then one of them is deleted). This can be observed in those cases where a neoclassical element combines with a native element, as in German *krypt-o-* as in *Kryptogesetz* 'crypto law' or *Kryptoverbot* 'crypto ban' as well as *-o-thek* in *Traumothek* 'dream-o-theque' or *Jazzothek* 'jazz-o-theque'.

All these differences – especially the facts that there are complex words that consist solely out of bound elements and the phonological differences – suggest that neoclassical word formation should be seen as a system that is different from native word formation in the base language in that it has its own rules and elements (Bloomfield, 1933; Domenig and ten Hacken, 1992; Fuhrhop, 1998, and many others). Aronoff (1976) assumed a nonconcatenative model in which neoclassical elements appear only in complex words and if an element appears in more than one complex word, one of them must be primary. Selkirk (1982) and Scalise (1986), for example, suggest that we have a class of stem compounds that differs from (native) word compounds. Lüdeling *et al.* (2002), on the other hand, argue that the class of neoclassical combinations, just like the class of native combinations, is not homogeneous and suggest a unified concatenative approach where Neoclassical is simply one feature among many.

Productivity

Some of the authors that assume different systems for native and neoclassical word formation also assume that neoclassical word formation is not synchronically productive (van Marle, 1985 even states that the notion 'productive' is only applicable to native elements in a language). The data suggests otherwise, however; qualitative aspects (roughly what Bauer,

2001, calls *availability*) as well as quantitative aspects (Bauer's *profitability*, see Baayen, 2001) show that neoclassical word formation is productive (see also Plag, 1999). Lüdeling and Evert (2005) show that neoclassical elements like nonmedical *-itis* have become productive within the last decade or so.

Neogrammarians

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

The success of a scientific endeavor is measured by the degree to which laws can be found for the phenomena being investigated. Linguistic science, emerging toward the beginning of the 19th century as a discipline in its own right, had to grapple from early on with determining the type and nature of the laws upon which to base its research procedure.

Wherever languages were studied, in ancient Greece and Rome, and especially in central Europe from the Middle Ages to the end of the 18th century, language in itself had rarely been the main objective. Researchers were primarily interested in fields of knowledge, for which language would provide

promising avenues that no other field could possibly offer.

With the emergence of Indo-European studies during the first quarter of the 19th century, matters changed dramatically. While Franz Bopp (1791–1867), Rasmus Rask (1787–1832), Jacob Grimm (1785–1863), and numerous other contemporary scholars from many European countries continued language investigations valuable for explaining the development of individual cultures and humanity in general, language for the first time had been focused on as something of primary importance.

The impressive achievements of the natural sciences inevitably stimulated researchers in the humanities to obtain results similarly significant for the study of languages. This was by no means a new idea. In the 17th century Francis Bacon (1561–1626), for example, had pointed in the right direction; this was acknowledged, for instance, by one of the most prominent beneficiaries 200 years later, August Friedrich Pott (1802–1887), who stated (1833: xxiiiff.) that "Bacon's procedure, that is, carefully observing and tirelessly seeking out analogies and laws, . . . has fortunately been employed at long last also in linguistics" (English translations, here and elsewhere, by the author of this article). Even more explicit was Gottfried Wilhelm Leibniz's (1646–1716) admonition about 100 years after Bacon: "The study of languages must not be conducted according to any principles other than those of the exact sciences" (Leibniz, 1768). But although these words were widely heard and heeded, they did not immediately lead to momentous results. Only after trial-and-error experimentation over a lengthy period of time did the notion gain ground that it was the individual letter – and through it the individual sound unit – on which linguists would initially have to focus to obtain the most tangible results. Once this insight had been converted into a rigorously employed procedure, linguistic science grew stronger by leaps and bounds. Jacob Grimm had believed that "the sound shift occurs in bulk, but never happens in each and every instance" (Grimm, 1822: 590). Yet, a few decades later, linguists used the term 'law'(*Gesetz*) more frequently, often to replace the term 'rule' (*Regel*), which until then had been deemed more appropriate for the description of historical events in the humanities. In the decades following Grimm's discovery of the sound shift, the number of exceptions that Grimm had to worry about had grown much smaller, made possible by a systematic scrutiny of known exceptions under sound-physiological viewpoints. A contemporary admirer of Grimm, Rudolf von Raumer (1815–1876), surpassed his master by comprehensively investigating the physiological properties of the individual sounds, thereby initiating a movement that culminated in removing the last exception to Grimm's Law by the Danish linguist Karl Verner's (1846–1896) discovery of another 'phonetic law': IE voiceless spirants become voiced in Germanic if in IE the stress did not immediately precede.

Interestingly, the conclusions that Verner drew from his observation, published in 1877, were also arrived at independently by Henry Sweet (1845–1912) and Eduard Sievers (1850–1932), even though neither of them seems to have been aware of their far-reaching significance. The search for further sound laws grew obviously widespread and was much more seriously pursued. The results both anticipated and actually obtained should explain the almost boundless enthusiasm felt by a group of young German linguists who thought they now had a reliable device to investigate the history of languages with a precision matching that of the natural scientists.

For various reasons, some older colleagues raised objections (cf. Curtius, 1885), calling the members of the group, slightly derisively, "*Junggrammatiker*" ('Neo-grammarians'). The name, much to the addressees' delight, rapidly became the trademark of those so named. The original group, loosely associated from about 1875 for several decades, comprised four Indo-Europeanists – Karl Brugmann (1849–1919), Berthold Delbrück (1842–1922), August Leskien (1840–1916), Hermann Osthoff (1847–1909) – and four Germanists – Wilhelm Braune (1850–1926), Friedrich Kluge (1856–1926), Hermann Paul (1846–1921), and Eduard Sievers.

They all were scholars of enormous productivity. Apart from shared general objectives, they were united in their interpretation of how sound changes in languages proceed, even though they individually placed different emphases on certain aspects involved.

The closest to a 'program announcement' is the foreword to *Morphologische Untersuchungen* Vol. 1 (Osthoff and Brugmann, 1878). The crucial item is the insistence on the need to rethink the methodology for investigation and to make the case for a more rigorous application of the sound law principle: "Only those who strictly adhere to the sound laws, this fundamental pillar of our entire science, do stand on firm ground in their research" (1878: xiv). All language changes, the Neogrammarians believe, are attributable to a sound law or the effect of analogy. By taking recourse to analogy, the Neogrammarians focus on a methodological device previously used, but, as they claim, less consistently applied. Analogy draws in psychological considerations. It involves transferring one particular form item from one member to other members of a grammatical paradigm without regard for historical

development. Thus, the MHG past tense singular forms of *neman – ich nam, du naeme, er nam* – did accept, unhistorically, the vowel form of the plural, â. The Neogrammarians admit only sound changes attributable to the operation of a sound law or due to analogy. These pronouncements were backed up by a formidable amount of hard-core research produced over many years, even by scholars not expressly proclaiming adherence to the Neogrammarian group. But the bulk of the research explaining sound changes by reference to sound law and analogy was the result of the ceaseless effort of the individual Neogrammarians.

Since there was no effort to launch a formal 'Neogrammarian movement,' it is understandable that some formulations of what the Neogrammarians stood for as a group were flawed or insufficiently explicit. Their primary objective was to conduct research. There were numerous casual statements, but the manifesto of 1878 remained the only formal presentation of the general theoretical approach. The loosely knit association of strongly independent-minded individuals hardly warranted a more systematic outlay of common endeavors. Leskien's rather cryptic sound law statement of 1876, the first offered by a Neogrammarian, presupposed more than it explicitly said:

> If exceptions are understood to mean those cases where an expected sound change did not occur due to certain recognizable causes, . . . there can of course be no objection to the statement that the sound laws suffer no exception. (Leskien, 1876: xxxiv)

In the same year, Sievers published his *Grundzüge der Lautphysiologie,* hailed by Johan Storm (1836–1920), who was the only contemporary phonetician comparable in stature to Sievers apart from Henry Sweet, as "an outstanding achievement . . . full of minute statements and meticulous observations which outdistance by far their predecessors" (cf. Streitberg, 1910: 584). Sievers did not employ the term 'sound law' yet, using *Lautwandel* ('sound change') instead. Sound change is treated on 19 of the book's 150 pages. Both regular and irregular changes are examined. The book was praised likewise by fellow Neogrammarians as a crucial advancement over the work of earlier phoneticians because "not only the individual sounds were treated, but also, which is of special importance for the understanding of the development of sounds, the way in which individual sounds combine to syllables, words, and sentences" (Paul, 1901: 124). Even today the work is an indispensable classic in the field.

Hermann Paul's own most influential contribution, *Prinzipien der Sprachgeschichte* (*Principles of the history of language*), provided a comprehensive model methodology of how language studies should be conducted. From the first edition of 1880 to the fifth and last edition of 1920, extensive revisions were made, but the elaborately devised foundations needed no essential change. The two basic principles, the concept of the exceptionless operation of the sound law supplemented by the analogy principle, are accorded a place of special prominence. They are shown in their interdependent role within the larger framework of language studies, which, according to Paul, have to be **historical** studies, if they deserve to be called **scientific** (cf. Paul, 1920: 20).

Paul elaborates on another point of central importance that is fully shared by all Neogrammarians, that "the creation of each language item is always the work of an individual" (1920: 18). Equivalently, in the "Neogrammarian creed" (Osthoff and Brugmann, 1878: xii), the case is made that language "has its true existence only in the individual and that, accordingly, all changes in the life of language can start only in the speaking individuals." The significant role of the individual was discovered long before the Neogrammarians, first by von Raumer's research (cf. Raumer, 1837, 1861). The Neogrammarians, while greatly profiting from scholars like him, thoroughly evaluated those previous achievements and added to them their own. From their interest in contemporary speech and dialectal variation, Paul and especially Sievers, but also other Neogrammarians, drew logical conclusions, paying closer attention to sound articulation and psychological considerations related to sound formation in particular and language production in general. One example for the resulting research is Hermann Osthoff's article on how physiological and psychological elements interrelate to provide the basis for adequate understanding of sound law and analogy, devices that he identifies "as the principal and most important leading norms of [language] research" (Osthoff, 1879: 3).

As they repeatedly acknowledged, the Neogrammarians owed a great deal to Wilhelm Scherer (1841–1886), particularly to his notion of the constancy of language development. August Schleicher (1821–1868) had taught that language history consists of (1) a prehistorical period of language formation and (2) a historical period of language decay (Schleicher, 1850: 10–11). Scherer, in contrast, insisted "that the distinction between development and decay is based on an error. I for my part have only noticed development, only history" (Scherer, 1868: x). Constancy of language development assigns to the speaking individual the central role in creating, shaping, and changing language. The Neogrammarians utilized the inherent implications by making this

'perfectly obvious idea' serve as one of the fundamental tenets of their research procedures: "that the psychic and physical activity of man when acquiring the language ... and when reproducing ... the sound images received into consciousness must have been essentially the same in all periods of time" (Osthoff and Brugmann, 1878: xiii).

The amount of criticism leveled against the Neogrammarians is considerable. It began shortly after their first writings appeared, continued well into the 20th century, and was alive even toward the end of the 20th century, although by then it occurred much less frequently and was characterized by a greater amount of objectivity.

One major objection was directed against the preoccupation with the sound side of language, seemingly at the expense of syntax and the meaning component. The plausible answer is that investigating syntax or semantics presupposes an elaborate investigation of sound and morphological structures. The Neogrammarians did exemplarily well on both counts and made significant advances in the field of syntactic studies (cf. Delbrück-Windisch, 1871–1888). They even ventured into the field of semantics (cf. Kluge, 1883).

More to the point was the criticism that the Neogrammarians tended to equate sound laws with natural rather than with historical laws. This unwarranted charge persisted for some time, even though earlier overstatements were swiftly rectified, for instance, by Paul (1920: 68).

Their insistence on the exceptionless operation of the sound law, however, was never substantially modified. Leskien's 1876 formulation remained valid and was widely accepted: "If any number of deviations are allowed, it amounts to simply admitting that the object of investigation, language, is inaccessible to scientific inquiry" (Leskien, 1876). Refinement over the years became necessary only with regard to a more precise definition of the specific conditions under which a particular sound law is applicable in a particular speech community.

Graziadio Ascoli (1829–1907), who was both somewhat critical and highly appreciative of what the Neogrammarians had achieved, put the overall criticism into proper perspective: "When checking into the entire controversy thoroughly and comprehensively without bias, it seems indeed almost impossible that it could ever exist" (Ascoli, 1887: 171).

The Neogrammarians did not invent the procedure of how to handle sound change, but they made it a much more effective tool for language research by examining all of its possible frameworks and ramifications and, above all, by showing through an abundance of practical investigations that the procedure works.

Neo-Gricean Pragmatics

Y Huang, University of Reading, Reading, UK

© 2006 Elsevier Ltd. All rights reserved.

In 1967, H. P. Grice delivered his Williams James Lectures at Harvard. In these lectures, Grice presented a panorama of his thinking on meaning and communication – what he called his "tottering steps" (Grice, 1989) toward a systematic, philosophically inspired pragmatic theory of language use, which has since come to be known as 'Gricean pragmatic theory.' Since its inception, Gricean pragmatics has revolutionized pragmatic theorizing and has to date remained one of the cornerstones of contemporary thinking in linguistic pragmatics and the philosophy of language. This article undertakes to present and assess a neo-Gricean pragmatic theory of conversational implicature, focusing on the bipartite model developed by Laurence Horn and the tripartite model advanced by Stephen Levinson (*see* **Implicature; Maxims and Flouting**).

The Hornian System

Horn (1984, 1989, 2004) developed a bipartite model. In Horn's view, all of Grice's maxims (except the maxim of quality) can be replaced with two fundamental and antithetical principles: the quantity (Q-) and relation (R-) principles.

(1) Horn's Q- and R-principles:
  (a) The Q-principle:
    Make your contribution sufficient.
    Say as much as you can (given R).
  (b) The R-principle:
    Make your contribution necessary.
    Say no more than you must (given Q).

In terms of information structure, the Q-principle is a lower bounding pragmatic principle that may be (and characteristically is) exploited to yield upper bounding conversational implicatures: a speaker, in saying '. . . *p* . . . ,' conversationally implicates that (for all he or she knows) '. . . at most *p* . . .' (*see* **Implicature**). The *locus classicus* here is those conversational implicatures that arise from a prototype Horn-scale. Prototype Horn-scales are defined in (2) (see Levinson, 1987, 2000):

(2) Prototype Horn-scales:
  For <*S*, *W*> to form a Horn-scale:
  (a) A(*S*) entails A(*W*) for some arbitrary sentence frame A.
  (b) *S* and *W* are equally lexicalized, of the same word class, and from the same register.
  (c) *S* and *W* are 'about' the same semantic relation, or from the same semantic field.

An example of Q-implicature is given in (3) (the symbol '< >' represents 'Q-scale'; '+>' represents 'conversationally implicates'):

(3) <all, some>
  Some of his friends took a taxi to the station.
  +> Not all of his friends took a taxi to the station.

On the other hand, the counterbalancing R-principle is an upper bounding pragmatic law that may be (and systematically is) exploited to engender low-bounding conversational implicatures: a speaker, in saying '. . . *p* . . . ,' conversationally implicates that (for all he or she knows) '. . . more than *p* . . .' (Atlas and Levinson, 1981). This is illustrated in (4):

(4) Have you got a watch?
  +> If you have got a watch and know the time, please tell me what time it is.

Neologisms

A Lehrer, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

New words frequently appear in English. Some words enter the language while others are used for a short time, or perhaps only once. During the last century, however, the rate of growth has accelerated. Neologisms draw on traditional word-formation devices, but some processes which were previously marginal have become common, for example, the new bound morpheme *-holic* as in the blend *workaholic*. Another process which has become productive is verb-headed compounds like *oil-paint*.

Neologisms Based on Common Word Formation Devices

One of the commonest word formation devices is compounding – combining two or more free morphemes. Compounds can be headed by any major lexical class, and all types are found in neologisms. A few examples are *jock talk* (N-N), *ripjob* 'negative publicity' (V-N), *dolphin-safe* (N-ADJ), *fail-safe* (V-ADJ), *red-hot* (ADJ-ADJ) *after-born* 'child born after the father's death' (P-ADJ), *over-quick* (P-ADV), and *off base* (P-N).

Traditional textbooks such as Marchand (1960), Selkirk (1982), Bauer (1983), and Spenser (1991) claim that verb-headed compounds are rare. The few existing ones are backformed by deletion of a suffix such as *-er* or *-ing* or formed by, for example, converting a compound noun into a verb. Examples are *sky-dive*, derived from *sky-diving*, and *carbon-copy*, which becomes a verb by being converted from a noun compound (Bauer, 1983: 208). The compound *self-destruct* is backformed from *self-destruction*. Although verb-headed compounds may have been rare in the past, this is no longer true. They occur so frequently in print and in spontaneous speech that it is reasonable to conclude that such compounds have become productive in recent years. In addition to the few listed in the works cited (*air-condition*, *baby-sit*, and *breast-feed*) are many other already conventional verb-headed compounds: *lip-read*, *gift wrap*, *copyread*, *custom-make*, *double-park*, *brain-wash*, *flight-test*, *test-drive*, *spot-check*, *window-shop*, *plea-bargain*, *stir-fry*, *chain-smoke*, *handpick*, *stage-manage*, *code-switch*, *guest-conduct*, *dry-clean*, *sun-dry*, *spot-weld*, *backpedal*, *channel-surf*, and *spell-correct*. Many verb-headed compounds are used in sports: *bounce-pass*, *pinch-hit*, *bucket-drive*, *speed-climb*, *jump-shoot*, *jump-pass*, and *kick-turn*. Many compounds are formed with the verb *hop*, as *in bed-hop*, *castle-hop*, *island-hop*, and with initial *self*:

self-identify, *self-calm*, *self-censor*, *self-limit*, *self-evaluate*, and *self-regulate*. Examples from spontaneous speech include *people-watch*, *reality-test*, *guilt-trip* (*she guilt-tripped us into doing that*), *trail-blaze*, *cattle-ranch*, and *oil-paint*.

Affixation

Another productive process is affixation, where a derivational suffix or prefix is attached to a word or a bound morpheme. Neologisms often use relatively unproductive affixes. Recent examples include *girl-**dom***, *astronaut**ess***, *market**eer***, ***be**jeaned*, ***re**tribalize*, and ***circum**stellar*. Some neologisms use unusual bases, as in *otherize* 'make someone different from other people'.

Conversion

Conversion is a process that turns a word belonging to one part of speech into another (e.g. noun → verb or verb → noun). Examples of noun-to-verb conversion are *to impact*, *to blackhole*, and *to network*. Examples of adjective-to-noun conversion are *a given* and *a nasty*.

Clipping and Acronyms

Clipping and acronyms have also become popular and productive in the 20th century. Clipping or shortening simply deletes part of a word: *veteran*, *veterinarian* → *vet*; *laboratory*, *Labrador* → *lab*. Although most clippings delete the end of the word, in some the beginning is removed: *omnibus* → *bus*, *airplane* → *plane*, and in a few, only the middle remains, such as *flu* ← *influenza*. Acronyms are formed by taking one or more of the first letters of a phrase, as in *SARS* (*severe **a**cute **r**espiratory **s**yndrome*), *AIDS* (*acquired **i**mmune **d**eficiency **s**yndrome*), *RAM* (*random **a**ccess **m**emory*). Many acronyms are created so that they form an existing word with a relevant meaning: *NOW* (***N**ational **O**rganization of **W**omen*), *BASIC* (***B**eginner's **A**ll-purpose **S**ymbolic **I**nstruction **C**ode*). Clipping and acronyms are extremely productive and efficient because they reduce long phrases and words, a process described by George Zipf (1949), who formulated a law which says that frequently used forms tend to become shorter.

Blends

Blends are underlying compounds which take one word and part of another word or parts of two words. The part of a word is called a splinter. Common examples are *beefalo* ← *beef* + *buffalo*, *smog* ← *smoke* + *fog*, *camcorder* ← *camera* + *recorder*, *sitcom* ← *situation* + *comedy*. The splinter is formally identical to a clipping, but whereas clippings function as full words, splinters do not. A sentence like *phone the vet* (*telephone the veterinarian*) is fine, but not *I am watching a sit* (*sitcom*) *right now*.

A few blends were recorded as early as the 19th century: *brunch* ← *breakfast* + *lunch* (1886 OED/MW), *slanguage* ← *slang* + *language* (1879 OED/MW), *solilioquacity* ← *soliloquy* + *loquacity* (1895 MW). Blends have become more common: *motel* ← *motor* + *hotel* (1925), *transceiver* ← *transmitter* + *receiver* (1934), *permafrost* ← *permanent* + *frost* (1943). Many of these etymological blends have become conventional words and speakers are no longer aware of their more complex sources. However, the speed of creating blends has accelerated so that blending can no longer be considered a marginal word formation device. Many novel blends are not defined, and readers and listeners are expected to figure out their source words and the appropriate meaning from the context.

The Structure of Blends

The commonest type of blend is a full word followed by a splinter: *wintertainment* ← *winter* + *entertainment*, *chatire* ← *chat* + *satire*, *vodkatini* ← *vodka* + *martini*. Blends can also begin with a splinter, followed by a full word: *narcoma* ← *narcotic* + *coma*, *cinemenace* ← *cinema* + *menace*.

Also common are blends consisting of two splinters. Two types are possible: (1) the beginning of one word is followed by the end of another word: *psychergy* ← *psychic* + *energy*, *hurricoon* ← *hurricane* + *typhoon* or *monsoon*, *cheriodical* ← *cheery* + *periodical*, or (2) both splinters are the beginnings of words: *biopic* ← *biographical* + *picture*, *sitcom* ← *situation* + *comedy*.

Blends typically show overlap in spelling and pronunciation. For example, in *wi**nter**tainment*, the bold letters belong to both source words: *winter* and *entertainment*. In *cine**m**enace*, the *m* belongs to both words. Sometimes the overlap is not simply of contiguous letters or sounds: ***astro**city* ← *astronaut* + *atrocity* and ***flus**tratred* ← *flustered* + *frustrated* distribute overlapping letters (and sounds) noncontiguously.

A fourth type of blend consists of complete overlap. Although nothing is missing, a part of the blend belongs to both words: ***sex**ploitation* ← *sex* + *exploitation*, ***pal**imony* ← *pal* + *alimony* 'money paid to an unmarried partner after breaking up', *coca**colo**nization* ← *Coca-Cola*® + *colonization*, ***cat**titude* ← *cat* + *attitude*, *W**heat**ables*® ← *wheat* + *eatibles*.

A fifth type of blend where one word is embedded in another is rare and has not increased in frequency. Examples are *entreporneur* ← *entrepreneur* + the clipping *porn*, *ambisextrous* ← *ambidextrous* + *sex*.

Some blends are eye blends, that is, they must be read: *leerics* ← *leer* + *lyrics*, *eracism* ← *erase* + *racism* (bumper sticker), *shampagne* ← *sham* + *champagne*. Blends may involve the deletion of some letters so that the neologism conforms to English spelling, as in *abusage* ← *abuse* + *usage*, instead of *abuseage*.

A very small number of blends consist of three source words. Examples are *intelevisionary* ← *Intel* + *television* + *visionary* (a journal article heading), *teenangstrel* ← *teenaged* + *angst ridden* + *minstrel* (Glowka *et al*., 2003: 339).

Although blends are sometimes created in casual conversation, they are more likely to appear in print, especially in advertising, product names, and magazine and newspaper headings. Product names: *Craisins*® ← *cranberry* + *raisins* 'dried cranberries', *Dijonnaise*® ← *Dijon* + *mayonnaise* 'mustard and mayonnaise', *Eurotard*® ← *Europe* + *leotard* 'style of dancewear', *Gogurt*® ← *go* + *yogurt* 'portable yogurt'; shop names: *Zoofari* ← *zoo* + *safari*, a gift shop at a zoo, *Thriftopia* ← *thrift* + *utopia*, the name of a thrift shop; hybrids of plants and animals: *broccoflower* ← *broccoli* + *cauliflower*, *cockapoo* ← *cocker spaniel* + *poodle*; events: *ARTstravaganze* ← *art* + *extravaganza*, an art auction. Halloween events included a *spooktacular event*, *Howl-o-scream*, a haunted house, and *Halloweek*, a week of scary movies.

Splinters Become Morphemes

Sometimes splinters occur in several blends. For example, *-topia* (← *utopia*) is found in *Fruitopia*®, *Thriftopia*, and *Artopia* (names of shops); *-ploitation* is found in *sexploitation*, *blaxploitation*, and *assploitation* (a criticism of a Nike ad showing a runner's derriere). If there are only a few examples, the process of analogy can account for the semi-productivity. However, splinters like *-thon*, *-holic*, *-gate* 'scandal', and *-scape* have spawned so many examples that it is plausible to argue that a new morpheme has been created (Lehrer, 1998).

-Thon ← *marathon* means something like 'event that lasts for a long time.' Other implications may be 'difficult' and 'fundraiser for charity.' Examples are *telethon*, *walkathon*, *bikathon*, *rockathon*, *dancethon*, *paint-a-thon*, *sew-a-thon*, *pianothon*, *performancethon*, *smilathon*, *soccer mom-athon*, *eat-a-thon*, *swimathon*, and *gore-a-thon* (in a review of Mel Gibson's *The Passion of the Christ*).

-Holic ← *alcoholic* 'addict' can be freely added to nouns and verbs, and it has produced dozens of neologisms: *workaholic*, *chocoholic*, *foodaholic*, *drugaholic*, *shopaholic*, *spendaholic*, *controlaholic*, *faxaholic*, *newsaholic*, *videoholic*, and many more.

-Gate 'political scandal' began with *Watergate* and generated *Irangate*, *Whitewatergate*, *Contragate,* and more recently *Skategate* 'scandal involving the attack on skater Nancy Kerrigan' (Glowka *et al*., 2000a: 190). French and Hungarian have borrowed *–gate* for their political scandals.

-Scape ← *landscape* 'view or representation of a scene' occurs in *seascape*, *mountainscape*, *oceanscape*, *rockscape*, and semantic extensions like *soundscape*, *spacescape*, *mindscape*, and *dreamscape*.

Most of these splinters occur at the end of the word, but a few can be initial, as *Mc* ← *McDonald's*, which has given rise to *McJobs* 'low-paying jobs', *McMansions* 'developments of large, expensive, identical houses', *McGarbage* 'waste created by disposable dishes, cutlery, and packaging', as well as the neologisms created by the McDonald Corporation, such as *McMuffin*. Another very popular initial splinter is *e-*← *electronic* (Safire, 2003), in dozens of items: *e-commerce*, *email*, *e-tail* (*electronic* + *retail*), *e-slammer* 'prison system with a web site' (Glowka *et al*., 2000b: 435), *e-bucks* 'electronic money', and *e-celebrity* 'a famous person promoting an Internet company' (Glowka *et al*., 2001a: 86).

Although some linguists and lexicographers consider these splinters to be prefixes or suffixes, they are best considered as bound bases, in particular, as combining forms. They are like many classical bases which must be combined with something else, such as initial combining forms *eco-* and *bio-*, or *-crat* and *-ology* (Bauer, 1983; Warren, 1990; Lehrer, 1998).

Trendy Neologisms

Neologisms often involve many kinds of wordplay: word-forming devices, rhymes, puns, allusions, and metaphors. For example, *yuppie* (*yuppy*), influenced by *hippie*, starts with the acronym *YUPP-* for *young urban professional people* with the added suffix *-ie* or *-y*, and this has generated many analogous terms, such as *buppie* ← *black urban professional people*, *maffy* ← *middle-aged affluent folks* (Glowka and Melançon, 2002: 316), In addition, *yuppie* has become the base of a verb, *yuppify*, and an adjective, *yuppie-ish*. *Malaprophesizing* ← *malapropism* + *prophesizing* (Glowka *et al*., 2001c: 417) 'telling the future inadvertently through verbal mistakes and slips' is a blend of two words, each morphologically complex.

The Internet has given rise to a large number of neologisms. A regular column in *American Speech*, 'Among the new words,' devoted two issues to neologisms concerning computers and the Internet in 1999 (vol. 74, no. 3, pp. 298–323 and no. 4, pp. 403–425). There are many compounds with *virtual* as the first

word or *techno-* and *e-*as initial combining forms. Analogous to *e-*we find *m-commerce* 'business conducted from a mobile telephone' (Glowka *et al.*, 2001c: 417). *Dot com* is a pronounced form of the Internet expression written as *.com*, which has spawned neologisms like *dot snot* 'arrogant young person with wealth derived easily through the Internet' (Glowka *et al.*, 2001c: 417). *Dot bomb* refers to a failed Internet business (Glowka *et al.*, 2001b: 307). *Dot-orging* is 'changing from a commercial establishment *.com* to an organization, *.org*'. As with blends, compound words may be segmented in unconventional ways. *Weblog* ← *World Wide Web* + *log* 'personal website full of commentaries' has been clipped to *blog* and converted to a verb *blogging* and an agentive *blogger*.

Many neologisms used in a highly specific context, such as a heading for a newspaper or magazine article, will disappear. But some will enter the language. Brand names will remain if the product succeeds. Other neologisms have entered English as permanent words, but are still informal, even slang, such as *yuppie* and *chocoholic*. A few, however, have become or will be permanent additions to Standard English and no longer elicit responses to newness or trendiness.

Nepal: Language Situation

M Hutt, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Successive decennial censuses of Nepal have counted the mother tongue speakers of an increasing number of languages: only 18 in 1981, but 31 in 1991 and 92 in 2001. This reflects a change in official attitudes to Nepal's linguistic diversity, with the old Panchayat-period (1962–1990) insistence on the exclusive dominance of Nepali giving some ground after the democracy movement of 1990 to the demands and assertions of minority ethnic and linguistic activists.

The censuses record that the proportion of the population that reports the national language, Nepali, to be its mother tongue, has fallen from a high of 58.4% (in a population of 15 million) in 1981 to 48.6% (in a population of 23 million) in 2001. Of the 92 languages enumerated in the 2001 census, however, only 16 recorded a total of mother tongue speakers in excess of 100 000:

Indo-Aryan Languages:
- Nepali 11 053 255 [48.6%]
- Maithili 2 797 582 [12.3%]
- Bhojpuri 1 712 536 [7.5%]
- Tharu 1 331 546 [5.9%]
- Awadhi 560 744 [2.5%]
- Bajjika 237 947 [1.05%]
- Rajbangsi 129 829 [0.58%]
- Urdu 174 840 [0.77%]
- Hindi 105 765 [0.47%]

Tibeto-Burman Languages:
- Tamang 1 179 145 [5.2%]
- Newari 825 458 [3.6%]
- Magar 770 116 [3.4%]
- Bantawa 371 056 [1.64%]
- Gurung 338 925[1.5%]
- Limbu 333 633 [1.4%]
- Sherpa 129 771 [0.58%]

This new listing was in some senses more reliable than previous ones: for instance, it distinguished between over 20 languages, most of them mutually incomprehensible, which had previously been lumped together as 'Rai-Kiranti'. On the other hand, it gave greater scope for minority groups to achieve a higher profile by returning their ethnic language as their mother tongue, thus presenting what is perhaps an exaggerated picture of Nepal's undeniable language diversity. In fact, five languages (of which four were Indo-Aryan) were claimed as mother tongues by 80% of the population, while 28 languages were claimed as mother tongues by fewer than 1000 people each and 30 by fewer than 10 000 people each. The claim of some of these smaller languages (e.g. Haryanwi, Hyolmo, Kisan, Lhomi) to be languages rather than dialects is disputable.

Nepali was brought into the region from the far west by Khas and Rajput immigrants sometime before the 10th century. It is therefore strongest in the western hill regions: in some districts, it is the only language spoken. Since its introduction, the Nepali language and its speakers have moved steadily eastwards, and Nepali is now firmly established as the lingua franca throughout the hills and mountains. The strong relationship between ethnic identity and language, and heightened ethnic awareness in Nepal during the 1990s, have influenced 2001 census returns, but levels of bilingualism with Nepali continue to grow nonetheless.

Tibetan and Tibetan dialects are spoken all along the northern border, while speakers of a great variety of Tibeto-Burman languages inhabit hill regions throughout central and eastern Nepal. These languages become increasingly diverse as one moves from west to east. Newari is still spoken by around half of the inhabitants of the towns of the Kathmandu valley, and the maintenance of the language and the development of its literature are buttressed by a strong politicocultural movement.

Languages common to populations both north and south of the India–Nepal border are current in the Tarai, and in some areas Hindi is used more commonly than Nepali as the lingua franca. Speakers of Maithili predominate in the lowland districts of the Sagarmatha and Janakpur zones, speakers of Bhojpuri in those of the Narayani zone. The Austro-Asiatic languages Santali and Satar are spoken by 40 000 people in districts adjacent to the border with Bihar and Bengal, while Tharu holds out among tribals in the remaining forests of the inner Tarai, particularly in the valleys of Dang and Deokhuri. In recent decades there has been a dramatic change in the composition of the population of the Tarai as hillspeople are resettled in the plains: this has led to a strengthening of the status of Nepali there.

Since the mid-20th century successive governments of Nepal have been concerned to standardize and develop Nepali as the national language, and have traditionally limited the use of other languages in most spheres of public life. The 1990 constitution reflected a softening in this attitude: Nepali is the *rastrabhasa*, the language of the nation, but the other mother tongues of Nepal are recognized as *rastriya*

bhasa, 'national languages,' too. Education in the mother tongue medium is permitted at preprimary level, and English is taught at secondary level, but Nepali remains the official medium of all state education. It is also the sole language of government and of the law courts. Nepali and English were the only languages used on Radio Nepal and Nepal TV until 1990, but since then news has been broadcast in a wide range of languages, including Newari, Maithili, and Tamang. Nepali is the main language of journalism, though the Nepali employed by official and government media is Sanskritized and high flown. The national literacy rate is 59.6%, up from 39% in 1991, though literacy rates vary widely between the various castes and ethnic groups, and between urban and rural populations. The majority of literature is published in Nepali, though significant quantities are available in other languages – notably Maithili, Newari, and Hindi. Sanskrit and classical Tibetan are important for religious purposes.

In hill regions, the trend has until recently been toward the diminution of minority languages, and most now show evidence of strong Nepali influence, particularly with regard to their word-stock. However, many minority communities, particularly those that speak Tibeto-Burman languages, are now concerned to protect and defend their languages, and many initiatives are under way to achieve these aims. In the Tarai, demands have been made for the constitutional recognition of Hindi as a second national language, but it is unlikely that these will be granted and in any case Maithili is a more potent ingredient of local identity.

Nepali, a member of the Indo-Aryan group of languages, is the national language (*rāṣṭra bhāṣā)* of Nepal, the state language of Sikkim, and the sole language of most ethnic Nepali communities in Bhutan and northeast India. It was previously known as Khas Kurā (the speech of the Khas) or Gorkhālī. Nepali probably has about 17 000 000 mother tongue speakers, and is a vital second language for approximately 7 000 000 speakers of other Nepalese languages, many of which are Tibeto-Burman.

Nepali was introduced into the central Himalaya by immigrants who entered from the northwest before the 10th century. Its ascendancy over the other languages of the region is linked to a process of political domination and cultural assimilation. Written in the Devanāgarī script, its earliest records are 13th-century royal inscriptions from far western Nepal, though Nepali was rarely used for literary purposes until the 18th century, and its first major work, the *Nepālī Rāmāyaṇa* of Bhanubhakta Acharya, was written in the mid-19th century.

Among the other major Indo-Aryan languages, Hindi is Nepali's closest cousin, and many literate Nepali speakers are proficient in Hindi. However, in its everyday vocabulary Nepali preserves many Sanskrit and Sanskrit-derived words (e.g., *ghām* 'sun', *khukurā* 'chicken', *ritto* 'empty') that have been displaced by Perso-Arabic loans in Hindi, and the Arabic and Perso-Arabic element of its lexicon is

bhasa, 'national languages,' too. Education in the mother tongue medium is permitted at preprimary level, and English is taught at secondary level, but Nepali remains the official medium of all state education. It is also the sole language of government and of the law courts. Nepali and English were the only languages used on Radio Nepal and Nepal TV until 1990, but since then news has been broadcast in a wide range of languages, including Newari, Maithili, and Tamang. Nepali, a member of the Indo-Aryan group of languages, is the national language (*rāṣṭra bhāṣā)* of Nepal, the state language of Sikkim, and the sole language of most ethnic Nepali communities in Bhutan and northeast India. It was previously known as Khas Kurā (the speech of the Khas) or Gorkhālī. Nepali probably has about 17 000 000 mother tongue speakers, and is a vital second language for approximately 7 000 000 speakers of other Nepalese languages, many of which are Tibeto-Burman.

Nepali was introduced into the central Himalaya by immigrants who entered from the northwest before the 10th century. Its ascendancy over the other languages of the region is linked to a process of political domination and cultural assimilation. Written in the Devanāgarī script, its earliest records are 13th-century royal inscriptions from far western Nepal, though Nepali was rarely used for literary purposes until the 18th century, and its first major work, the *Nepālī Rāmāyaṇa* of Bhanubhakta Acharya, was written in the mid-19th century.

Among the other major Indo-Aryan languages, Hindi is Nepali's closest cousin, and many literate Nepali speakers are proficient in Hindi. However, in its everyday vocabulary Nepali preserves many Sanskrit and Sanskrit-derived words (e.g., *ghām* 'sun', *khukurā* 'chicken', *ritto* 'empty') that have been displaced by Perso-Arabic loans in Hindi, and the Arabic and Perso-Arabic element of its lexicon is

largely confined to law, war and weaponry, and governance and monarchy. Similarly, English loans are generally less common in Nepali than in Hindi, partly because Nepal was never colonized by the British.

Unlike Hindi, Nepali distinguishes between existential (*chanu*) and definitive (*hunu*) functions of the verb 'to be', e.g., *pānī ho?* 'is this water?', *pānī cha?* 'is there [any] water?' Like Bengali, it uses numeral classifiers, e.g., *tīnjanā mānche* 'three [-person] men', *tīnvaṭā mec* 'three [-object] chairs' and accords feminine gender only to female human nouns. It forms most plural nouns through the affixation of *harū*; and generally forms negative verbs by the adaptation of verb endings, e.g., *ma jānchu* 'I go', *ma jãdina* 'I do not go'. Four honorific grades plus a royal honorific are available for personal pronouns. Clauses are commonly linked by the use of infinitives and participles and seldom by conjunctions: thus, *H. vah ādmī jo kal āyā* 'the man who came yesterday' is *Ne. hijo āeko mānche* 'the yesterday having-come man'.

Nepali lacks the H. phonemic distinction of /ś/ /v/ from /s/ /b/. Regional dialects have been identified but dialectal variation is not strong. Nepali has influenced the Tibeto-Burman languages of the region more than it has been influenced by them (Sprigg, 1987), though there are a few loanwords from Newari, e.g., *jhyāl* 'window' and some features of syntax and intonation may reflect Tibeto-Burman influence.

Netherlands Antilles: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The Netherlands Antilles is a group of five islands formerly known as the Dutch West Indies. They are an overseas territory of the Kingdom of the Netherlands, with full internal affairs autonomy since 1954. Geographically, there are two groups of islands within the Netherlands Antilles. The first group comprises Bonaire and Curaçao (which form the so-called ABC islands among the Leeward Islands off the coast of Venezuela). The second group has Saba, St Eustatius, and St Maarten (among the Windward Islands, in the northeastern part of the Caribbean). The northern half of St Maarten, Saint-Martin, belongs to France, as part of the overseas department of Guadeloupe. Until 1986 Aruba was part of the Netherlands Antilles, but it is now separate from it.

Before the first Europeans appeared here, the islands were inhabited by Arawaks and Caribs. In the 17th century, the islands were colonized by the Netherlands, and plantations were established using the labor of African slaves until slavery was abolished in 1863. The economy is now based mainly on the oil industry and tourism.

The population is 218 126 (according to a July 2004 estimate). The largest part of the population descends from the African slaves who were once traded here for work. A smaller portion of the population comprises Caribbean Indians, Europeans, and Asians. The official language is Dutch on all islands. The most widely used language on the Leeward Islands is Papiamentu (a creole formed by Dutch, English, Spanish, and Portuguese), which is spoken by more than 80% of the population. On the Windward Islands, the local language is English, which is also spoken in all other parts of the Netherlands Antilles. Spanish, Virgin Islands Creole English, and Sranan are also spoken everywhere. The language of instruction in schools is Dutch on the Leeward Islands and English and Dutch on the Windward Islands. On the Leeward Islands, Papiamentu has been introduced fully in kindergartens and is taught in primary schools as a subject. The adult literacy rate is 96.7%.

Netherlands: Language Situation

J W M Verhoeven

This article is reproduced from the previous edition, volume 5, p. 2779, © 1994, Elsevier Ltd.

Compared to many other countries, the language situation in the Netherlands is straightforward in that there is only one national, official language – that is, Dutch. The designation of Dutch in the language itself is '*Nederlands*,' and it is used as the language of government, administration, education, and culture by around 15 000 000 people. Dutch emerged as the country's standard language in the 17th century from the Holland and Brabantine dialects. The characteristics of modern standard Dutch are quite homogeneous, although regional differences in pronunciation have to be recognized.

Matters of linguistic policy in the Netherlands are the responsibility of the Dutch Language Union, which is an intergovernmental institution founded in 1980 in order to promote the integration of Dutch language and literature in the Netherlands and the Dutch-speaking community in Belgium, that is, in Flanders. It coordinates policies regarding Dutch spelling, grammar, dictionaries, terminology, the teaching of Dutch as a foreign language, and literature.

The main foreign language taught at secondary schools is English. In addition, German and French are widely offered, and occasionally it is possible to take Spanish. Some schools also provide the opportunity to study Arabic and Turkish. The medium of instruction at university level is Dutch. It is, however, common practice to teach language-related subjects for language degrees in the target language.

In Friesland, the northeastern province of the Netherlands, Frisian (that is, West Frisian) is recognized as an official language besides Dutch: it is spoken either as a first or a second language by around 400 000 people, or two-thirds of Friesland's total population. Efforts to increase the status of Frisian have met with some success. In 1980, the language became a compulsory subject at primary schools in the province, and it is offered as an optional subject at 25% of secondary schools in the region. Furthermore, there are regular religious services, radio and television broadcasts, and newspaper articles in Frisian.

Very Early Studies and an Overview

One of the earliest observations of disorders of language is in the Pharonic medical document, *The Edwin Smith Surgical Papyrus*, purchased in 1862 by Edwin Smith and translated in 1930 by James H. Brestead (Wilkins, 1964). Although the papyrus itself dates from the 17th century B.C., as Egypt was moving toward the zenith of the Pharonic period, it derives from an earlier text c. 3000–2500 B.C. Case 22 (out of 48) describes the patient who, having sustained a blow to the temple sufficient to break the skull, is rendered aphasic: "If thou callest to him and he is speechless and cannot speak" (Breasted, 1930). A cuneiform clay tablet c. 1500 B.C., described an event in the life of the Hittite king Mursilis II: while riding in his chariot during a thunderstorm, he was rendered speechless. Mursilis attributed this to an intervention by a storm god; the description of the event suggests a transient ischemic episode, from which the king later recovered.

As described by Benton and Joynt (1960), there are examples of loss of speech in the Hippocratic corpus circa 400 B.C., in Latin texts c. 1st century A.D., in a number of Latin texts from the 10th to the 14th century, in Renaissance texts such as the Schenck compendium of 1558, in various 17th century texts such as the Schmidt and Rommel cases, and in 18th-century books such as the Wepfer compendium of 1727 (based on material from the 1660s). The late 18th and early 19th century phrenological

Compared to many other countries, the language situation in the Netherlands is straightforward in that there is only one national, official language – that is, Dutch. The designation of Dutch in the language itself is '*Nederlands*,' and it is used as the language of government, administration, education, and culture by around 15 000 000 people. Dutch emerged as the country's standard language in the 17th century from the Holland and Brabantine dialects. The characteristics of modern standard Dutch are quite homogeneous, although regional differences in pronunciation have to be recognized.

Matters of linguistic policy in the Netherlands are the responsibility of the Dutch Language Union, which is an intergovernmental institution founded in 1980 in order to promote the integration of Dutch language and literature in the Netherlands and the Dutch-speaking community in Belgium, that is, in Flanders. It coordinates policies regarding Dutch spelling, grammar, dictionaries, terminology, the teaching of Dutch as a foreign language, and literature.

The main foreign language taught at secondary schools is English. In addition, German and French are widely offered, and occasionally it is possible to take Spanish. Some schools also provide the opportunity to study Arabic and Turkish. The medium of instruction at university level is Dutch. It is, however, common practice to teach language-related subjects for language degrees in the target language.

In Friesland, the northeastern province of the Netherlands, Frisian (that is, West Frisian) is recognized as an official language besides Dutch: it is spoken either as a first or a second language by around 400 000 people, or two-thirds of Friesland's total population. Efforts to increase the status of Frisian have met with some success. In 1980, the language became a compulsory subject at primary schools in the province, and it is offered as an optional subject at 25% of secondary schools in the region. Furthermore, there are regular religious services, radio and television broadcasts, and newspaper articles in Frisian.

Very Early Studies and an Overview

One of the earliest observations of disorders of language is in the Pharonic medical document, *The Edwin Smith Surgical Papyrus*, purchased in 1862 by Edwin Smith and translated in 1930 by James H. Brestead (Wilkins, 1964). Although the papyrus itself dates from the 17th century B.C., as Egypt was moving toward the zenith of the Pharonic period, it derives from an earlier text c. 3000–2500 B.C. Case 22 (out of 48) describes the patient who, having sustained a blow to the temple sufficient to break the skull, is rendered aphasic: "If thou callest to him and he is speechless and cannot speak" (Breasted, 1930). A cuneiform clay tablet c. 1500 B.C., described an event in the life of the Hittite king Mursilis II: while riding in his chariot during a thunderstorm, he was rendered speechless. Mursilis attributed this to an intervention by a storm god; the description of the event suggests a transient ischemic episode, from which the king later recovered.

As described by Benton and Joynt (1960), there are examples of loss of speech in the Hippocratic corpus circa 400 B.C., in Latin texts c. 1st century A.D., in a number of Latin texts from the 10th to the 14th century, in Renaissance texts such as the Schenck compendium of 1558, in various 17th century texts such as the Schmidt and Rommel cases, and in 18th-century books such as the Wepfer compendium of 1727 (based on material from the 1660s). The late 18th and early 19th century phrenological

contributions of Franz Joseph Gall and his colleague Johann Gaspar Spurzheim and the phrenologically inspired case studies of Alexander Hood, along with the more orthodox medical work of Claude François Lallemand, Jean Baptiste Bouillaud, Jacques Lordat, and Marc Dax, inaugurated a period of intense interest in the brain localization of language functions, culminating in the classic work of Paul Broca, Theodor Meynert, Carl Wernicke, Henry Charlton Bastian, John Hughlings Jackson, and others during the late 19th century. Although questioned on occasion by wholist views such as those of Henry Head and Kurt Goldstein, the localization model presevered until, by the second half of the 20th century, classical neurolinguistics became firmly entrenched in both clinical and experimental neuroscience research.

Medieval and Renaissance Neurolinguistics

The longest lasting model of functional brain localization has been Medieval Cell Doctrine. Derived in part from the ideas of the Alexandrian physicians Herophilus (c. 270 B.C.) and Erasistratus (c. 260 B.C.) and in part from Aristotle's concepts of sensation, perception, cognition and memory, Medieval Cell Doctrine, in its particular variant, Ventricular Theory (MCD-VT), was first articulated by the Church Fathers Nemesius (c. 400), Poseidonius (c. 370), and St Augustine (354–430), with later Arab contributions, particularly from Avicenna (980–1037). MCD-VT was a model based on fluids (spirits) and fluid flow for the apparent reason that thoughtful early philosophers must have realized that something in the brain must move from place to place in order to be responsible for the separable functions of creating a mental image (*sensus communis*), engaging cognitive operations, and storing the result in memory, a model loosely based upon Aristotelian descriptions of mental functions. These early philosophers evidently hypothesized that something passes from sense organs to the brain, then through the brain and back to muscle effectors; the animal spirits (in the Galenic sense) were likely as good a candidate as any available. MCD-VT had become sufficiently entrenched in medicine and philosophy that it was the dominant model of brain function well into the 17th century, seen for example in the mechanistic model advocated by René Descartes (1596–1650). In point of fact the basic principle of MCD-VT – that there are different functions located in different places in the brain – as well as other vestiges of this two-millenia-old idea, remain as recognizable features of contemporary cognitive neuroscience and neurolinguistics.

From the 11th century through the Renaissance, one finds textual discussions and graphic representations, some worthy of being identified as Renaissance art, of MCD-VT; accompanying these one occasionally finds what one could call neuropsychological case reports, usually interpreted in terms of MCD-VT, typically although not invariably accepting the standard model, which placed memory in the third ventricle. Memory, in turn, was typically described as verbal memory, making it apparent that many of these cases would square with what 20th-century authors called aphasia. Language, or more precisely speech output, was, *ab propagatio*, situated in the third cell or ventricle, an association perhaps derived from Galen's correct belief that motor functions were a property of the cerebellum. Whether the cause or the result of a view of memory as verbal memory, it is clear that memory and language were so closely connected that memory disorders were language disorders and vice versa. For example, consider this case from an 11th-century manuscript: Guillaume de Conches (1080–1150) reported that Solin had spoken of a man who suffered traumatic injury to the last cell of the brain and who fell into an amnesia so profound that he had forgot his own name. Another report, by Brassavola, from the 16th century, refers to a Corsican soldier who, after recovery from a severe head wound, could not remember anything, could not speak, and was so out of his mind that he could not understand nor say anything. Many of these cases were compiled by Johannes Schenck (1584) and by Johannes Wepfer (1727), both of whom are discussed below. Others were compiled in Jules Soury's *Le Système Nerveux Central* (1899).

Eventually the Ventricular Theory component of Medieval Cell Doctrine fell by the wayside, the demise beginning in the 17th century, as some of its key components (e.g., animal spirits flowing through hollow nerves or in and between empty ventricles) were challenged both by experimental and by theoretical arguments. However, other aspects of the model, for example, the concepts of localization, of information flow, of the links between memory, language, and motor function, and the idea that memories are stored images, were not only never challenged but seem to have become absorbed into post-Renaissance models of brain function. From at least the 16th century, a correlation between language disorders and particular cerebral lesions (as opposed to ventricular or simply 'in the brain' lesions) has been recognized. The late-Renaissance physician Johannes Schenck von Grafenberg (1530–1598) published '*Observationes medicae de capite humano*' (Basel: Frobeniana) in 1584; it is a treasure-house of neuropsychological observations, including a number

of observations on language disorders. There are contributions from 20 Greek authors, 5 classic Latin authors, 11 medieval Arabic and Jewish authors, 37 barbarian Latin authors, 292 recent Latin authors, and 139 nonmedical authors. Schenck also included 64 unpublished cases reported by his contemporaries. His encyclopedic collection of clinical information, all with an explicit bibliographic citation, has no counterpart in its time or earlier. At least 16 of Schenck's observations mention language disorders *qua* memory disorders subsequent to brain lesions. Although many case descriptions are superficial, some include very clear observations, demonstrating that neuropsychological knowledge was in fact far more advanced than one might have surmised. Armand Trousseau, a contemporary of Broca, cited Schenck as an early physician who appreciated the essential nature of aphasia.

A sampling of Schenck's cases (see Luzzatti and Whitaker, 1996) illustrate the level of description in this early neurolinguistic work. Reporting a 14th-century case from Gentile da Foligno and a 16th-century case from Cristobal deVega, Schenck notes the selective loss of the alphabet and object names, accompanied by loss of reading and writing. Another 16th-century case from Tertius Damianus reports that a patient studied his letters again, an early written documentation of rehabilitation. Schenck recorded an impressive 16th-century description by Conrad Lycosthenes of his own right hemiplegia and aphasia, described as a loss of voice. The inability to speak lasted 12 days, and the severe motor deficits lasted 3 months. Lycosthenes had even lost rote-memorized passages such as the Mass but had retained internal language and thinking; he was able to communicate by pointing, with his left hand, to letters in sequence in order to form words. Evidently one of his friends had hit upon the idea of writing the alphabet down on a board as a communication aid. Citing Jakob Oethaeus, Schenck observes that the tongue may retain its motor functions when word memories have been lost, thus establishing very early the dissociation between articulatory control and language production that became a focal point of discussions in the early 19th century. Clearly the Renaissance's neurolinguistic legacy to the 17th century's so-called age of reason and scientific discovery was considerable.

17th and 18th Centuries: Johannes Jakob Wepfer

Wepfer (1620–1695) was an acquaintance of Thomas Willis and, although less well known than either Schenck or Willis, was in fact one of the most important 'neurologists' of the 17th century. Author of several works on stroke, Wepfer's work that is pertinent to the history of neurolinguistics is '*Observationes medico-practicae de affectionis capitis internis et externis*,' which was written around 1690 but available only in a posthumously published version of 1727. The book is notable for its accuracy, colorful clinical descriptions, and systematic organization. In observation #98, 'loss of memory,' Wepfer describes a transient language disorder with selective impairment of proper names, accompanied by a syntactic disorder; no acalculia nor other neuropsychological deficits were reported. The following is translated and paraphrased from the Latin:

> A 53-year-old man returning from a walk vomited several times. He spoke both in Latin and German, but his words did not relate to the topic of conversation nor were they answers to questions put to him. He continuously repeated the same utterances, (became) stuck on the pronunciation of words, and frequently complained that he could not express his thoughts in words. A month later he suddenly forgot all names, even his own. He could not name any object, neither in Latin nor in German. He gave the impression that he was able to recognize objects and people but the words he uttered were alien and incoherent.
>
> After one more month, his memory was almost completely restored; his faculty of hearing and repeating was adequate and he could count, add, subtract and divide without error. Occasionally, he could not find the proper names of a person or a places as quickly as usual and from time to time he could not find some of the little words of the sentence. He is able read again and writes full texts without hesitation. His faculty of judgement is normal and he was able to fulfill his duties as before. When he was talking, I could observe him from time to time violate syntactic rules and, against the structure of German sentences, he would antepose one word to another (word-order errors) and sometimes he could not complete some little word (inflectional morphology errors). In general he recognised his errors and corrected them (Luzzatti and Whitaker, 1996: 161–162).

In addition to its interest as an early study of agrammatism, Wepfer's case is also exemplary of most, but not all, classical aphasia research on grammatical or syntactic disorders up to the 1960s: a descriptive summary of the omission or misuse of function words or inflections in spontaneous or elicited speech samples of patients with an expressive aphasia. It is exemplary as well of an analysis that made no attempt to explain the disorder but rather described it, a tradition in neuropsychology that still has its advocates.

Wepfer's Observation #102, a loss of memory followed by melancholia, is instructive for its neuropsychological detail:

> A most reverend 44-year-old cleric sat in judgement on a controversy proposed by a peasant; however, when he tried to express his judgement, he could not find the words he wanted to communicate his thoughts. From that moment on, he lost his memory so much that he no longer was able to call the onlooker by his name nor could he name any object. He clearly saw the colours and features of objects and drawings presented to him, but he could neither read nor combine letters. All his remaining outward and inner sensations were normal. He recognised his loss of memory and the errors he made while speaking. There was no trace of paralysis; he could pronounce every letter, even the R.
>
> The site of suffering is neither in any nerve pertaining to both types of sensation, because he hears, sees, tastes, etc., nor in the nerve subserving speech, because he can pronounce all sounds, even the R, nor in the brain stem or spinal cord, because there is no trace of movement disorder. It seems to be located in that part of the brain, where the images of objects are organised. These may be retrieved, as from a store, and, when required, supplied by means of the mnestic faculty. What part of the brain this might in fact be, cannot be defined, but clearly it is not an involvement of the entire brain, because the patient is not drowsy, and has lost neither his ingenuity nor his understanding (Luzzatti and Whitaker, 1996: 162).

Compared to the similar collection (in organization and focus) of clinical cases compiled by Schenck, Wepfer's cases were more carefully selected, most were followed by autopsy, and the etiological-pathogenic commentary is notably advanced in relation to the *Zeitgeist* of the 17th century, particularly in comparison with Wepfer's contemporary, Thomas Willis. Wepfer is arguably the first modern physician to discuss the nature of cognitive functions, particularly language, using a neuropsychological approach. To our knowledge, he is the first to consistently report the side of the lesion and the presence of aphasia; however, Wepfer does not overtly discuss a relationship between language disorders and left hemisphere lesions, in spite of the fact that he often wrote, "*paralysis dextri lateris, cum loquelae impedimentum*." Luzzatti and Whitaker (1996) speculated that perhaps the philosophical milieu in which Wepfer was studying and working did not lead him to appreciate the relevance of his own observations to laterality issues; on the other hand, perhaps his silence on the matter of hemispheric asymmetry was out of a concern for an unwelcome reception by the church for what would have obviously been a materialistic viewpoint. After all, Galileo had been accused less than 30 years earlier, and the squares of Europe still smelled of the stakes of the Inquisition.

Other 17th-century neurolinguistic reports worth mentioning include one by Johann Schmidt (1624–1690), a case of severe fluent paraphasia with right hemiparesis; the patient showed good recovery of oral language and agraphia, but not for his reading disorders:

> A leading citizen among us, Nicholas Cambier, an old man of 65 years, was seized with a very severe attack of apoplexy which all his attendants feared would lead to his death. Upon returning home, it was evident that he has had a metastasis to the right side producing hemiplegia; the tongue started doing its task with difficulty, so that he could say many things but in an incorrect way. He was incapable of expressing the feelings of his mind; he substituted one word for another so that his interlocutors had difficulty in determining what he wanted. Furthermore, he could not read written characters, much less combine them in any way. He did not recognise a single letter nor could he distinguish one from another. But it is remarkable that, if some name were given to him to be written, he could write it promptly, and that with the correct spelling for any of the language he previously knew. However, he neither could read what he had written, even though it had been done by his own hand, nor could distinguish or identify the characters. For if he were asked what letter this or that was or how the letters had been combined, it seemed as if he had done it only by chance or through his habit of writing. It appeared that he wrote without deliberation. No teaching or guidance was successful in inculcating recognition of letters in him. It was otherwise with a certain stone cutter in our country, Wilhelm Richter came to see me after his apoplexy receded because he was not able to read at all or to recognize letters. However, he learned the alphabetic elements of the language again in a short time. He then combined them and attained perfection in his reading (Benton and Joynt, 1960).

Another is Peter Rommel's (1643–1708) 1682 study of a patient whose spontaneous output was reduced to a few automatisms; however, serial speech, prayers, and comprehension were preserved. Considering the cases by Schmidt, Rommel, Schenck, and Wepfer, it is clear that scientists of the 16th and 17th centuries were able to clearly distinguish language disorders from general cognitive deficits, language production versus comprehension deficits, lexical from sound or letter errors, and both syntactic and morphological impairments, not to mention differential bilingual impairments. Although the neuropsychological modeling needed to complete these analyses did not begin to develop until the beginning of the 19th century, the 18th century also witnessed more systematic clinico–pathological observations of memory disorders and language disorders, with frequent report of the cooccurence of aphasia with right-sided paralysis. Giovanni Baptista Morgagni, widely regarded as the founder of clinico–pathological

correlations, reported several cases of aphasia in his 18th-century compendium on the seats and causes of disease.

Franz Joseph Gall and His Times

Whatever else may be said of the 18th century, it is clear that by its end, medicine and had fully accepted the idea of the discrete localization of functions in the brain, or, in the vernacular of the time, faculties. Although much has been written about Franz Joseph Gall's (1758–1828) contribution to neuroscience, not a lot is known about the roots of his ideas. It has been argued that there is a close parallel between the faculty psychology of Thomas Reid (1710–1796) and the craniological faculties proposed by Gall; it has also been pointed out that there is a commonality between the (hundreds of) physiognomic characteristics proposed by Johann Christian Lavater (1741–1801) and Gall's faculties. Gall's idea that growth patterns of the cortex, hypertrophy or atrophy, could impress themselves on the inner table of the skull, and thus by inference be, 'readable' as bumps on the skull, appears to have been directly borrowed from Lavater.

Charles Bonnet (1720–1792), a Swiss naturalist and philosopher approvingly referred to by Gall, authored books on botany, zoology, and psychology; Bonnet's psychological ideas were consistent with those of Etienne Bonnot de Condillac (1715–1780), a leading exponent of French sensationalism, an extreme form of empiricism. Bonnet believed that every faculty – sensitive, moral, or intellectual – is linked to a bundle of fibers in the brain. According to Bonnet, every faculty has its own laws, which determine its mode of action; not only does every faculty have its own fasciculus of fibers in the brain, but every word has its own fiber in the brain. In light of these ideas already present in the 18th century, Gall's craniology, or faculty neuropsychology, appears to be a logical if somewhat fanciful development.

Gall had, theoretically, described a division between two aspects of the language function and had proposed two distinct localizations. On a skull shelved in the University of Vienna medical museum Gall inscribed in an elegant penmanship the various faculties of the mind. At the back of the left bony orbit (eye socket) but not the right one (an odd coincidence, since we have no reason to think that Gall discussed any version of the lateralization of brain functions) he wrote *Wortsinn*, the memory for words, and *Sprachsinn*, the faculty of spoken language. This distinction was implicit in the work of Wepfer discussed earlier. Thus, Gall had assigned two separate but adjacent localizations to motoric (*sprachsinn*) and lexical (*wortsinn*) language functions, which he rather imaginateively localized in the frontal lobes of the brain. Gall's reasoning was taken from the essence of craniological theory: (1) he thought he had observed that people with high verbal skills exhibited 'cow's eyes' eyes that seemed to stick out because of shallow eye sockets; thus (2) he reasoned that a well-developed language faculty would cause a protuberance of the inferior, anterior frontal lobe, which in turn would push on the skull, making the eye sockets shallow. Although Gall's entire craniological, later phrenological, doctrine was challenged by the scientific community, this putative localization of language was not directly challenged, even though in fact it should be regarded as a mistake, an error in reasoning using the craniological method. It was well known at the time that the backside of the eye sockets do not abut the frontal lobe; a great deal of sinus cavity lies between the two. It is quite impossible that a frontal brain bump could impinge upon the eye sockets.

The most important scientific challenge to craniology/phrenology came from Flourens's experiments demonstrating that animals whose cerebellums he had lesioned still exhibited copulatory behavior. This was clear empirical evidence against Gall's localization of the reproductive faculty in the cerebellum and is arguably one of the principle reasons why many scientists rejected craniology/phrenology. Gall refused to accept Flourens's evidence; the scientific community, particularly Jean-Baptiste Bouillaud, who is discussed below, accepted it. On the other hand, curiously from the standpoint of 'good science,' Bouillaud not only accepted Gall's localization of language function in the frontal lobe, he championed it unceasingly, right up to 1861 when Broca's publication seemed to vindicate Gall's model. Evidently it was the accumulating evidence that frontal lesions typically led to speech disturbances, documented by Lallemand, Bouillaud, and other from the 1820s on, that kept the phrenological language model alive until the great paradigm shift of the 1870s. Although Gall stated his belief that the clinico–pathological correlation of brain lesions to language disturbances could furnish evidence in support of his model, and he did in fact study two cases of sword injury to the frontal lobe referred by Napoleon's surgeon, Dominique Larrey, Gall himself evinced little direct interest in language and brain relations. However, in the hands of that stalwart of medicine Jean-Baptise Bouillaud, as well as those of the relatively unknown country doctor Alexander Hood, the phrenological model based upon Gall's ideas did serve to preserve studies of brain–language

correlations through the first two-thirds of the 19th century.

From the 1820s to Broca

Pierre Paul Broca (1824–1880) focused on disorders of speech production (*langage articulé*) because, before the 1860s, one did not discuss disorders of language comprehension. Language was constructed as speech output, and the rest, what could have been discussed under the rubric 'comprehension,' fell under the notion of 'mind,' which at the time was in the province of philosophy, religion, and nascent psychiatry (e.g., the alienists). This of course had been tradition since the time of Galen; the primary difference was that now the location had shifted from the third cell or ventricle as in Medieval Cell Doctrine to the frontal lobe as in Gall's craniology, later phrenology.

From the 1820s on, both the orthodox medical and the unorthodox phrenological journals were filled with case reports of expressive language impairments arising from stroke and trauma, with and without autopsy evidence of the involvement of the frontal lobes. That is to say, Gall's hypothesis that the frontal lobes are the seat of language was hotly debated for over 40 years before Broca's famous articles. The publications of Jean-Baptiste Bouillaud, François Lallemand, François Broussais, Marc Dax, and Jacques Lordat are the more familiar; however, there were dozens of obscure medical practitioners publishing these reports. Alexander Hood was one such lesser known researcher.

Alexander Hood

To better appreciate the phrenological contribution to neurolinguistics, it is instructive to look at what practicing phrenologists actually did; with that in mind, let us consider one of Spurzheim's intellectual legacies, 'The Phrenological journal and miscellany' (PJM), the house organ of the Edinburgh Phrenological Society, founded in 1820 by George Combe (1788–1858). In 1824, an obscure medical practitioner and phrenologist from Scotland, Dr Alexander Hood, published a remarkable case history of one Adam M'Conochie, who, subsequent to a CVA in the left frontal lobe, had become what by the 20th century would be called a 'Broca's Aphasic.'

Patient Adam M'Conochie, a 48-year-old gardener in Dankeith, Scotland, sustained a mild left hemisphere CVA the morning of May 31, 1824. Hood first saw the patient that same afternoon and took a brief history from his wife, who noticed "a striking deficiency . . . in the use . . . of language, which in fact was limited to a few words."

Hood questioned his patient about his complaint but was unable to get a satisfactory response "on account of his utter inability to give a description in language of the state of his mind." To indicate where the problem lay, M'Conochie obligingly raised his (left) hand to the left side of his head, and, pointing particularly to the temple behind the angle of the eye, said there was "something about it." One can only imagine Hood's reaction as an aphasic patient signalled the site for the *Organ of Language* as having a problem! Not to mention that, given the presumed left hemisphere locus of the stroke, M'Conochie's left arm and hand undoubtedly functioned better than the right.

An outline of Hood's entries documenting the course of his patient's difficulties are arguably the first time that recovery from aphasia has been carefully chronicled:

> June14th: M'Conochie continues to improve in reading, to which he applies himself assiduously; but there is apparently not quite so much improvement in his powers of conversation.
>
> June 21st: . . . by now the patient can read tolerably well, with the exception of a few words that he cannot pronounce. He cannot, however, repeat a sentence or even a syllable of the Lord's prayer, with which he was formerly familiar. He moves his legs and arms with perfect facility and apparent vigour; but says the right hand is 'dumb.'
>
> July 2nd: M'Conochie has been melancholic; his right arm and leg are weak; he can read pretty well, but cannot repeat anything which may have been committed to memory; there are still some words which he cannot pronounce. A strong degree of excitement seems to give him temporary command of a few words which he has not in his calmer moments.
>
> July 10th: His reading is not materially improved since last report, but can read verses much better, having obviously acquired an extensive addition to his vocabulary. He can use both arms and hands equally well and perceives little difference with regard to strength, but a striking difference with regard to sensation. This day, for the first time, by means of language, he has been able to make himself intelligible with respect to the state of his feelings since the commencement of his complaint.

At the end of his case report, Hood included parts of the discussion of three other cases, reported earlier in the same journal, arguing that one may separate or fractionate two features of the organ for language, based upon the evidence from these patients. Although one patient had forgotten in general the names of objects with which he was familiar, yet when the name of a thing was given in his hearing, he was capable of recollecting it for a few seconds of time, so as to be able to pronounce it again. Hood notes

that this is quite different from case R. W., who very often could not recollect the word long enough to enable him to pronounce it a second time, thereby demonstrating that the paralytic affection was more severe in this case than the other.

Hood argues that the case of M'Conochie and the case of R. W., considered together, bear the most pointed analogy with respect to the phenomenon of language. One must bring a degree of credulity to the localization, of course; in Hood's terms, however, it was perfectly credible that a patient could indicate the site of a lesion by pointing to the spot on his head. Hood claimed that in one patient the damage "affected a much greater surface"; accordingly, the organ of language was not exclusively affected, for some of the muscles that assist in articulation were paralytic, from the impediment which was conspicuous in the pronunciation of some words. Hood also took note of the loss of sensation on right side of face, numbness of arm and particularly of the hand, without any loss of power of motion. Thus, for Hood, cases R. W. and M'Conochie "mutually illustrate each other." In R. W.'s case the affliction was confined exclusively to the organ of langauge; in M'Conochie's case, the organ of language was also affected, though not quite so severely; however, the lesion extended further, involving the area controlling the muscles of articulation (p. 92).

In sum, by comparing two different aphasic cases, Hood provided empirical evidence for the fractionation of the organ of language into a part directly controlling the articulatory muscles, another controlling verbal expression, and a third controlling the memory or ideas for words. This was a remarkably prescient experimental conclusion, employing a theoretically coherent, albeit implausible, clinico–pathological correlation. Hood concludes with a homily advising that one needs to have a good theory before studying the brain, so that the evidence of impaired function may be properly related to the elements of the theory. In his case, the theory was the map of the phrenological organs neatly painted on a plaster bust.

The paper describing the case of Adam M'Conochie, the fourth of six that Alexander Hood published in the PJM collectively titled "Mr. Hood's Cases of Injuries of the Brain, Case 4th – July 28, 1824," generates historical interest on several counts: its contribution to the technique of clinico–pathological correlation, its indebtedness to the phrenological movement in Scotland launched by Spurzheim and Combe, its use of aphasic data to argue for both the modularity and the fractionation of language, and, not least, the coincidence that it was published on the very day and year that Paul Broca was born, July 28, 1824.

Jean-Baptiste Bouillaud

Bouillaud (1796–1881), a cardiologist, was also a phrenologist, and as well one of Gall's close circle of friends; between 1825 and 1861 he gave a number of papers at meetings of the French academy of medicine, defending the frontal lobe localization of language. He published a paper in 1825 providing clinical arguments that the two organs for language were situated in the anterior lobes of the brain. Although Bouillaud has been credited with having made the first observation of 'internal' and 'external' speech, or what he termed the "power of creating words as signs of our ideas and that of articulating these same words" (Harrington, 1987), it is clear that he borrowed the concept from Gall (who may or may not have picked it up from earlier writers such as Wepfer). Bouillaud may, however, have been the first to attribute one to gray and the other to white matter tissue. In his own words:

> The tongue and its related organs in the act of speech can be separately paralyzed, that is to say, without the other parts being affected simultaneously . . . the loss of speech depends now upon the loss of the memory of words, now upon the loss of the muscular movements by which speech is composed, or, what comes perhaps to the same thing; now upon a lesion of the gray matter and now upon that of the white matter of the anterior lobes (translated in McHenry, 1969: 490–491).

After the death of F. J. Gall in 1828, Bouillaud was the major medical figure in France who supported the concept of cerebral localization; he thus became the major link between Gall and Broca (Harrington, 1987). Broussais, one of the more prestigious physicians in France, had pronounced in favor of phrenology, but most other recognized scientists had sided with Flourens against Gall. Not generally appreciated is that Bouillaud did not uncritically accept Gall's theory: e.g., he sided with Flourens on the matter of the role of the cerebellum and further, in 1830, agreed with Flourens that phrenology was a pseudoscience. Clearly, Bouillaud had distanced himself from phrenology *per se*, while maintaining the truth of the theory of cerebral localization with respect to language. There has been a tendency for historians to jump from Bouillaud's 1825 paper to the Auburtin-Gratiolet-Broca discussion of 1861. One reason, as Clarke and O'Malley (1968) *inter alia* noted, is that Bouillaud's views did not gain wide acceptance during the three-decade interval in question; however, he was not by any means ignored. In the pages of the French academy of medicine publications of 1826, 1827, 1839–1840 and 1847–1848, Bouillaud debated the concept of cerebral localization, using language

and its frontal lobe location, with important clinical and experimental opponents such as Andral, Flourens, Pinel (fils), Cruveilhier, Lallemand, Rochoux, Rostan, and Castel. It seems evident that any medical researcher during this 30+ year period was frequently confronted with the theory of cerebral localization, particularly that of language. It is also apparent that people were quite aware of the fact that, if the proof of the localization of language were to be established, then the entire enterprise of cerebral localization would be viable and legitimate (e.g., see Cruveilhier, 1839).

Although the major purpose of Bouillaud's 1825 paper was to support Gall's theory of a relation between loss of speech and a lesion of the frontal lobes, the paper is of additional interest because of the discussion of the major issues of functional–anatomical correlation, particularly for language. After a brief introduction, Bouillaud vehemently attacked the prevailing view (Flourens's view) of the hemispheric localization of motor functions, arguing that to accept the idea that the hemispheres control motor functions is not enough because different parts of the brain control different types of movements; this is particularly clear for movements of the tongue and eye. Bouillaud's stated purpose in his paper was actually to demonstrate the brain's control of speech movements. He claimed to be able to demonstrate, first, that speech movements may be compromised separately from those of the limbs and second, which specific part of the hemispheres are involved in the control of speech movements. By way of finding evidence to support his first claim, he described clearly and sharply, and he seems to be the first to do it, the principle of double dissociation: two activities are functionally separate if they can be disrupted in isolation or independently from each other.

Bouillaud's proof came from the description of three cases in which a severe speech disorder was not accompanied by any limb disorder or by any defect of the movements of the tongue that are required for any act besides speech. Somewhat in contrast to his own premises, Bouillaud seemed to predict the existence of a pure motor disorder of the movement of the mouth and tongue (what we might call a dysarthia of speech) in isolation from any articulatory deficit; but he actually only presented half of his claimed double dissociation, omitting to present the opposite case of motor disorder of limbs and/or of tongue without any speech deficit. Bouillaud then moved straight to the major purpose of his work: to identify the specific area of the hemispheres that is responsible for speech motor control, i.e., following Gall's theory, the frontal lobes. But how could one demonstrate this? Surgical lesions in animals do not help, because animals do not have speech (a rebuttal to the work of Flourens), and this kind of experiment is not possible in humans; anatomo–functional correlations of cerebral lesions in humans can help for this purpose. He thus suggested testing the hypothesis of a localization of speech motor control, and/or of language (because he does not seem to have had a clear insight about the interface between thought and motor speech control), in the frontal lobe. In this context he demonstrated a clever insight, clearly defining the principle of necessary and sufficient condition to test anatomo–functional correlations: if frontal lobes are crucial to direct speech movements, two conditions must be satisfied, i.e., when frontal lobes are affected, speech must be affected; but also, when frontal lobes are spared, the same must happen for speech movements.

Following this principle, Bouillaud described several (as he called them) positive and negative cases, in which the anatomo–clinical correlation fully corresponded to his expectations; he then tested the localization of speech in the frontal lobes on the basis of two neurological and neuropathological sourcebooks (Lallemand, 1820, 1822; Rostan, 1823). Analyzing the data from these two authors, Bouillaud confirmed his theory both for the positive and for the negative observations. He even seemed to show surprise as to why Lallemand and Rostan had not themselves come to the same conclusion, in the face of such clear evidence.

Bouillaud's paper continues with a short debate on the nature of speech production, where he addresses the problem of the interaction between lanaguage and speech. After discussing Gall's principle of the location in the frontal lobes of the memory for words, Bouillaud differentiates his position from Gall's, arguing that while the frontal lobes are the site of both these distinct faculties, the gray matter is the site for the organ of the verbal representations and the white matter the site of the speech motor output. It should be emphasized how outstanding these observations are in the context of orthodox medicine of the mid-1820s.

Neutralization

T A Hall, Indiana University, Bloomington, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

'Neutralization' is the term first proposed by members of the Prague School in the 1930s referring to the suspension, in a particular context, of a contrast that is maintained in other contexts (*see* **Prague School**). A similar phenomenon in which contrasts between morphological categories is eliminated in a particular environment is referred to as syncretism (*see* **Syncretism**). Two types of neutralization are usually distinguished, namely contextual neutralization and positional neutralization (see Trubetzkoy, 1939).

Contextual neutralizations suspend some contrast in the context of neighboring sounds. For example, in many languages there is a contrast between voiced and voiceless sounds in certain environments (e.g., word initially and/or word finally), but this contrast cannot be observed in the neighborhood of a voiced or voiceless sound, e.g., Serbian contrasts /p/ vs. /b/ word finally in /stub/ 'pillar' vs. /skup/ 'expensive', but only /p/ surfaces before voiceless sounds, e.g., [sr̩b] 'Serb' vs. [sr̩pski] 'Serbian'.

Positional neutralizations occur when a contrast is suspended at the edge of some constituent (e.g., word, syllable). A standard example illustrating this type of neutralization in phonology is found in Dutch and German. In both of these languages, there is a contrast between voiceless and voiced obstruents, e.g., /p t k f s/ vs. /b d g v z/ that can be observed word initially (e.g., German *Pass* /pas/ 'passport' vs. *Bass* /bas/ 'base') and word internally (e.g., German *Ente* /ɛntə/ 'duck' vs. *Ende* /ɛndə/ 'end'). In word-final position, many German and Dutch words end in a voiceless obstruent (e.g., German *bunt* /bʊnt/ 'colorful'), but in neither language are there words that end phonetically in a voiced obstruent. In German and Dutch, there are many word pairs that show an alternation between voiced and voiceless obstruents, e.g., German *Tag* [taːk] 'day' vs. *Tag-e* [taːgə] 'day + plural'. This word pair shows that in the singular the underlying /g/ devoices to [k] because it is in syllable-final position and in the plural the /g/ stays [g] because it is in syllable-initial position. In this example, the contrast between voiced and voiceless obstruents is neutralized in syllable-final position. The alternations mentioned above are captured in phonology with some formal mechanism, e.g., a rule of final devoicing, i.e., [−sonorant] → [−voice] / ___ $]_{\sigma}$. Final devoicing is an example of a phonological rule of (positional) neutralization.

Neutralizations typically eliminate the marked member of a contrast (*see* **Markedness**). For example, the final devoicing example mentioned above eliminates voiced obstruents from occurring in syllable-final position because voiced obstruents are [+voice] (as opposed to [−voice]). The output of a neutralization need not belong to one of the two sets of sounds that contrast. For example, in American English /t/ and /d/ contrast word initially and finally (e.g., *tip* vs. *dip* and *write* vs. *ride*), but this contrast is neutralized to the flap [ɾ] in intervocalic position before an unstressed vowel, e.g., *writer* and *rider* both surface with [ɾ]. In Prague School phonology, the output of a neutralization was assumed to be an archiphoneme (see Trubetzkoy, 1939 and Lass, 1984), which is an abstract entity that subsumes the totality of the properties that are common to the contrasting phonemes.

The typical context for positional neutralizations is word- (or syllable-) final position. In contrast, rules that neutralize contrasts in word- (or syllable-) initial

'Neutralization' is the term first proposed by members of the Prague School in the 1930s referring to the suspension, in a particular context, of a contrast that is maintained in other contexts (*see* **Prague School**). A similar phenomenon in which contrasts between morphological categories is eliminated in a particular environment is referred to as syncretism (*see* **Syncretism**). Two types of neutralization are usually distinguished, namely contextual neutralization and positional neutralization (see Trubetzkoy, 1939).

Contextual neutralizations suspend some contrast in the context of neighboring sounds. For example, in many languages there is a contrast between voiced and voiceless sounds in certain environments (e.g., word initially and/or word finally), but this contrast cannot be observed in the neighborhood of a voiced or voiceless sound, e.g., Serbian contrasts /p/ vs. /b/ word finally in /stub/ 'pillar' vs. /skup/ 'expensive', but only /p/ surfaces before voiceless sounds, e.g., [sr̩b] 'Serb' vs. [sr̩pski] 'Serbian'.

Positional neutralizations occur when a contrast is suspended at the edge of some constituent (e.g., word, syllable). A standard example illustrating this type of neutralization in phonology is found in Dutch and German. In both of these languages, there is a contrast between voiceless and voiced obstruents, e.g., /p t k f s/ vs. /b d g v z/ that can be observed word initially (e.g., German *Pass* /pas/ 'passport' vs. *Bass* /bas/ 'base') and word internally (e.g., German *Ente* /ɛntə/ 'duck' vs. *Ende* /ɛndə/ 'end'). In word-final position, many German and Dutch words end in a voiceless obstruent (e.g., German *bunt* /bʊnt/ 'colorful'), but in neither language are there words that end phonetically in a voiced obstruent. In German and Dutch, there are many word pairs that show an alternation between voiced and voiceless obstruents, e.g., German *Tag* [taːk] 'day' vs. *Tag-e* [taːgə] 'day + plural'. This word pair shows that in the singular the underlying /g/ devoices to [k] because it is in syllable-final position and in the plural the /g/ stays [g] because it is in syllable-initial position. In this example, the contrast between voiced and voiceless obstruents is neutralized in syllable-final position. The alternations mentioned above are captured in phonology with some formal mechanism, e.g., a rule of final devoicing, i.e., [−sonorant] → [−voice] / ___ $]_{\sigma}$. Final devoicing is an example of a phonological rule of (positional) neutralization.

Neutralizations typically eliminate the marked member of a contrast (*see* **Markedness**). For example, the final devoicing example mentioned above eliminates voiced obstruents from occurring in syllable-final position because voiced obstruents are [+voice] (as opposed to [−voice]). The output of a neutralization need not belong to one of the two sets of sounds that contrast. For example, in American English /t/ and /d/ contrast word initially and finally (e.g., *tip* vs. *dip* and *write* vs. *ride*), but this contrast is neutralized to the flap [ɾ] in intervocalic position before an unstressed vowel, e.g., *writer* and *rider* both surface with [ɾ]. In Prague School phonology, the output of a neutralization was assumed to be an archiphoneme (see Trubetzkoy, 1939 and Lass, 1984), which is an abstract entity that subsumes the totality of the properties that are common to the contrasting phonemes.

The typical context for positional neutralizations is word- (or syllable-) final position. In contrast, rules that neutralize contrasts in word- (or syllable-) initial

position are rare. The explanation for this asymmetry is that there is a strong tendency in natural languages to preserve underlying segments (and sequences of segments) in word-initial position because this is a perceptually salient position (see the psycholinguistic literature on the importance of word-initial position in processing, e.g., Hawkins and Cutler, 1988). Thus, if languages make an effort to preserve phonological material in contexts in which this material is more salient, then a preservation of segments (and contrasts) in word-initial position is to be expected (*see also* the recent literature on this topic in **Pragmatics: Optimality Theory,** e.g., Beckman, 1997).

It is important to distinguish between neutralization and defective distribution. The latter concept is exhibited by a segment that fails to surface in some of the environments occupied by other members of its class. For example, English [ŋ] has a defective distribution because, unlike the other nasals /m n/, it cannot surface word initially or after /s/.

New Caledonia: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Located in the South Pacific Ocean, east of Australia, New Caledonia comprises a main island, Grande Terre, which is divided into a South and a North Province, and a number of smaller islands, known collectively as Îles Loyauté (the French translation of the original name, Loyalty Islands, given to them by early British explorers). After Papua New Guinea and New Zealand, it is the third-largest territory in the Pacific. Although the oldest archaeological remains suggest New Caledonia may have been settled from about 1300 B.C.E. onwards, other clues, such as the linguistic diversity on Grande Terre or a Paleolithic barrow on the Île des Pins, point to a much earlier date. The first contact with the West came in 1774, when Captain Cook, on his second Pacific expedition, landed on Grande Terre, baptizing it New Caledonia, for the island reminded him of his native Scotland. In 1853 the French admiral Fébvrier-Despointes claimed the islands for his country, and in 1946 New Caledonia became an overseas territory of France. The official language of New Caledonia is French, but 37 other languages are currently in use on the islands; the linguistic situation is more homogeneous on the Îles Loyauté than on Grande Terre, where a large number of languages are spread over a relatively small space. All the autochthonous languages of New Caledonia belong to the Eastern Malayo-Polynesian group of the Austronesian family. The indigenous languages with the most speakers are Dehu (10 000 speakers on Lifou and 5000 in Nouméa, the capital city), Nengone (6100 speakers on Mare), Paicî (5500 speakers around Koné and along the coast between Poindimié and Ponérihouen), Ajië (5000 speakers in Houailou), and Xârâcùù (5000 speakers in Canala and Thio). The majority of the other languages, however, are spoken by fewer people; the tonal language of Cemuhî, for example, is spoken by 2500 islanders, Fwaî by 1000, and Yuaga by 2000. Other language communities are even smaller: Pwapwa, for instance, counts only 130 speakers, Vamale 150, and Arhâ 250. Because of the scarcity of speakers, some of the languages are under threat of extinction: this is true for Arhö and Haeke, which are spoken by fewer than 100 people. Two languages, Waamwang and Zire, are already considered extinct; there are a few who have learned the latter, but only as a second language. There are also two creoles spoken on New Caledonia: Bislama is an English-based creole; Tayo, a French-based one, is used as a first language by some who normally are also bilingual in French and as a second language by others, mainly immigrants from Wallis Island. According to the 1996 governmental census, almost 40% of ethnic Melanesians, who constitute 44.1% of the entire population, no longer speak their mother tongue. Kanaks, as Melanesians are called in New

position are rare. The explanation for this asymmetry is that there is a strong tendency in natural languages to preserve underlying segments (and sequences of segments) in word-initial position because this is a perceptually salient position (see the psycholinguistic literature on the importance of word-initial position in processing, e.g., Hawkins and Cutler, 1988). Thus, if languages make an effort to preserve phonological material in contexts in which this material is more salient, then a preservation of segments (and contrasts) in word-initial position is to be expected (*see also* the recent literature on this topic in **Pragmatics: Optimality Theory,** e.g., Beckman, 1997).

It is important to distinguish between neutralization and defective distribution. The latter concept is exhibited by a segment that fails to surface in some of the environments occupied by other members of its class. For example, English [ŋ] has a defective distribution because, unlike the other nasals /m n/, it cannot surface word initially or after /s/.

The majority of the other languages, however, are spoken by fewer people; the tonal language of Cemuhî, for example, is spoken by 2500 islanders, Fwaî by 1000, and Yuaga by 2000. Other language communities are even smaller: Pwapwa, for instance, counts only 130 speakers, Vamale 150, and Arhâ 250. Because of the scarcity of speakers, some of the languages are under threat of extinction: this is true for Arhö and Haeke, which are spoken by fewer than 100 people. Two languages, Waamwang and Zire, are already considered extinct; there are a few who have learned the latter, but only as a second language. There are also two creoles spoken on New Caledonia: Bislama is an English-based creole; Tayo, a French-based one, is used as a first language by some who normally are also bilingual in French and as a second language by others, mainly immigrants from Wallis Island. According to the 1996 governmental census, almost 40% of ethnic Melanesians, who constitute 44.1% of the entire population, no longer speak their mother tongue. Kanaks, as Melanesians are called in New

Caledonia, have increasingly opted for French, thus favoring the emergence of diglossia, in which the indigenous languages are the lower-status ones. Access to schooling was guaranteed to all Kanaks only in 1953; nowadays all adults are considered bilingual, but levels of proficiency are still varied. Many of the islanders, including a large number of those of European descent, use a regional variant of French to communicate. Caledonian French has phonetic idiosyncrasies and possesses a few grammatical constructions, calqued on Kanak languages, that distinguish it from standard French, but the differences are fewer than those, for instance, between standard French and Quebec French. Immigrants make up 21.3% of the population of New Caledonia; thus Polynesians, Indonesians, and Vietnamese, among others, constitute nonterritorial linguistic and cultural minorities, which tend to be centered around the capital city of Nouméa. English plays an important role in New Caledonia, which, it may be worth remembering, is surrounded by at least 25 million Anglophones. A large section of the school-educated population speaks English, as do a number of Kanak communities, whose inhabitants' ancestors were Christianized by British missionaries; also a good part of the immigrant population knows English.

French, being the official language of New Caledonia, is used in formal circumstances, and it is the language of government, law, administration, and education. At times, during official meetings on the Îles Loyauté, the local Kanak tongues may be used, but only for oral communication. A program has been launched to prepare Melanesians who want to go into politics at either the municipal or the provincial level, but the courses are available only in French. In fact, French remains the language of education in general, even though the Nouméa Agreement (1998) between France and New Caledonia stipulates that the Kanak languages are also languages of culture and education. In 1985 a number of Kanak primary schools opened with the aim of promoting Kanak identity and culture by conducting the teaching in the local languages, but disappointing results led to their early closure – only the one in Canala remains open to this day. In the early 1990s the provinces launched a plan to integrate indigenous languages in mainstream education; this means that a few lessons, such as geography or art, are taught in one of the local languages, but nothing is being done to spread literacy among young Kanaks in their mother tongue. Only 5% of students in secondary education in 2001 followed courses in one of the four languages available at that level (Ajië, Dehu, Nengone, and Paicî). At the University of New Caledonia, teaching is conducted exclusively in French, although Dehu and Ajië have been taught there since 1999 and Nengone and Paicî since 2000. A Kanak Language Academy is also being planned for the not too distant future, and there are plans to start preparing teachers to teach local languages at both the primary and the secondary levels. It must be noted that often many of the Melanesians themselves feel that only education entirely in French can guarantee academic success and secure access to work. As for the media, all the papers and periodicals are in French, and television and radio also broadcast in French, although Radio Djiido, associated with the Kanak Socialist Liberation Front, has a few programs in the local languages. As a last point, it can be added that even if the two provincial governments with a Kanak majority should decide to favor the use of a Melanesian language, they would face the problem of the multiplicity of languages present in New Caledonia, and they could never hope to quell completely the importance of French, notwithstanding France's decision to adhere to the European Charter for Regional or Minority Languages, which will prompt a change in the linguistic policies adopted in French overseas possessions.

New Religious Movements

S Raine and S A Kent, University of Alberta, Edmonton, Alberta, Canada

© 2006 Elsevier Ltd. All rights reserved.

New religions emerge as either schisms off existing faiths or creative compositions of unique (or previously unsynthesized) material (Stark and Bainbridge, 1987: 126–128). In either set of circumstances, these new religions must establish themselves amid skeptical if not hostile social environments, and their use of language reflects this challenge. Consequently, researchers find unique uses of language as new religions attempt to establish their credentials, identify their goals, undertake projects, maintain their members, and deal with critics and defectors. Scholars differ as to whether the term 'new religions' should apply only to groups emerging in the late postcolonial period or can apply to the first appearances of older faiths into societies, but in any case the language issues share common features.

In their efforts to establish themselves, new religions develop terms of legitimacy. Indeed, the very designation of groups as 'religious' usually is something that their leaders desire since the designation brings with it degrees of societal legitimacy while deflecting pejorative labels (such as sect or cult) that their critics often prefer (Kent, 1990). Moreover, the religious designation allows these groups to establish or create spiritual lineages that sanctify their existence in the context of the existing sociocultural landscape (Kent, 2003). The language of naming groups, for example, illustrates numerous legitimation strategies. Some new religions choose names that indicate their role as restorers of the true faith – for example, the Restored Church of God, which is a schism of the Worldwide Church of God (Barrett, 2001: 503); Uganda's deadly Movement for the Restoration of the Ten Commandments of God (Barrett, 2001: 94–95); and the schism of gay and lesbian Mormons titled The Restoration Church of Jesus Christ (Shields, 1990: 274–276). Others use language that identifies their reputed role as unifying the faiths, such as the Holy Spirit Association for the Unification of World Christianity, founded by the controversial Korean leader, Sun Myung Moon (Barker, 1984: 42); or Church Universal and Triumphant, based on the reputed communications received from the Ascended Masters to Elizabeth Clare Prophet in America (Whitsel, 2003). Similarly, many groups assert an international or global appeal, such as the controversial International Churches of Christ (Giambalvo and Rosedale, 1997), the increasingly mainstream Christian organization called the Worldwide Church of God (Tkach, 1997), and the Hindu-based International Society for Krishna Consciousness (Brooks, 1989). At least one group, the science-fiction based Church of All Worlds, claims cosmic appeal (Barrett, 2001: 401–405).

Numerous other organizations attempt legitimation by using scientific language in either their names or doctrines – for example, Christian Science; Scientology and its foundational book, *Dianetics: the modern science of mental health* (Hubbard, 1950); the United Church of Religious Science in the United States (Melton, 1991: 58–60); and the School of Economic Science, based in the United Kingdom (Barrett, 2001: 266–276). Using a related strategy, various new religions insist that they are scientifically based. Among them are the Raelians, who claim that all members of the human race are alien clones (Barrett, 2001: 390–395), and Transcendental Meditation, which claims that its meditation techniques are scientific procedures that produce measurable improvements in personal and social life (Barrett, 2001: 276). Regardless of what legitimation strategies new religions use, they intend to carve out a social space for themselves in sociocultural environments that contain (potential) spiritual supporters, competitors, and critics.

Language plays an equally important role in how many new religions define their goals. As a recruitment strategy, these new religions may describe their goals as being purer, more effective, and more important than those of the groups that likely provide their largest recruitment pools. For example, amid the floundering anti-Vietnam-War movement in the early 1970s, numerous new religions adopted the radical rhetoric of youth protest culture in order to attract converts to them (Kent, 1993, 2001: 44–150). Followers of the teenaged guru, Maharaj Ji, frequently heard him speak about his message bringing peace to the planet, using language very similar to slogans that were commonplace in contemporary youth counterculture (Kent, 2001: 48–54). Likewise, Scientologists widely distributed a claim by their group's leader, L. Ron Hubbard, that Scientology techniques could end war (Kent, 2001: 99). Also in that same period, the Children of God's founder, David Berg, spoke about his group as offering the disillusioned youth of the period a "revolutionary new life" within his organization, drawing heavily from the politically revolutionary rhetoric that was standard parlance among activist youth. Whatever variations the technique took, the use of rhetoric among the new

religions of the 1970s helped converts believe that they were furthering a social revolution whose political efforts (they believed) largely had failed.

Regardless of the projects that new religions undertake, these groups often view their efforts as being uniquely spiritual and pure. Consequently, a set of binary terms frequently develop that identify and separate the 'pure' from the 'impure' and 'us' versus 'them.' Members of the Hare Krishnas, for example, who call themselves 'devotees,' refer to nonmembers as 'karmies,' which implies that their secular, materialist lives create bad karma for their next rebirths (dasa, 1985: 346). Scientologists refer to nonmembers as 'WOGs' or "raw meat preclears" (Hubbard, 1975: 471, 335) and themselves as "specialist[s] in spiritual and human affairs" (Hubbard, 1975: 369). Followers of David Berg, who (throughout the 1970s) called themselves Children of God, referred to people in society as 'Systemites' (Van Zandt, 1991: 51, 129). When members used claims of missionary work to procure donations from Systemites, they were 'provisioning' by 'spoiling Egypt' (Van Zandt, 1991: 36, 39).

An essential aspect of elitism or 'specialness' that is so common among new religions is the frequent use of familial language. Leaders assume parental roles, and members assume new names and take on sibling roles toward one another. Examples are numerous (and certainly occur within more established faiths): Reverend Moon and his wife are the "True Parents" to their flock (Barker, 1984: 80–81, 168, 195), and Elizabeth Clare Prophet was 'Guru Ma,' 'Mother,' or 'Divine Mother' to Church Universal and Triumphant members (Paolini and Paolini, 2000: 55, 59; Whitsel, 2003: 5, 38). Remarkably, members of Scientology's notorious Guardian's Office in the 1970s, whose members carried out burglaries against governmental and nongovernmental offices in the United States and Canada, concluded their internal memos with the word 'love' before signing their names (U.S. District Court for the District of Columbia, 1979).

The use of familial, 'loving' language contributed significantly to groups' maintenance of members by creating for them a 'fictive family' atmosphere (Cartwright and Kent, 1992). Equally binding are group experiences of (what outsiders might call) linguistic nonsense – collective chanting in foreign languages that members do not understand, unintelligible high-speed chanting, or glossolalia (speaking in tongues; Samarin, 1972). For example, English-speaking adherents to the form of Japanese Buddhism known as Soka Gakkai chant for extended periods long verses of transliterated Japanese (Barrett, 2001: 304). Church Universal and Triumphant members (and many potential converts) participated in 'decreeing,' which were rapidly spoken prayers allegedly to destroy evil and enhance positive energy (Whitsel, 2003: 36). Finally, many Christian groups affiliated with Pentecostalism practice 'speaking in tongues,' in which people supposedly possessed by the Holy Spirit speak in unknown, heavenly languages (Hood *et al.*, 1996: 201–204; Samarin, 1972).

Whatever spiritual interpretations the believers of various faiths may assign to these uses of language, from a social scientific standpoint they illustrate crucial examples about attribution theory. According to attribution theory, groups place potential converts in social circumstances for which they have no interpretive frameworks (i.e., unusual prayer or chanting situations) and then give them a religious (as opposed to a psychological or linguistic) interpretation (Hood *et al.*, 1996: 32–33; Proudfoot and Shaver, 1975: 325–326). Without competing interpretive frameworks, people often accept the religious (mis)attribution and join the group. As members, they continue participating in these activities, thereby strengthening their commitment.

Closely related to a group's use of language to create situations that are ripe for (mis)attribution are "thought-terminating cliché[s]" that psychiatrist Robert J. Lifton (1961: 429) identified as "loading the language." These simple, clichéd phrases constrict individuals by reducing complex "human problems ... into brief, highly reductive, definitive-sounding phrases, easily memorized and easily expressed" (Lifton, 1961: 429). They assuage many of the questions and concerns of group members by both providing easily remembered platitudes and dividing the world into dichotomous absolutes. These dichotomies may strengthen group cohesion but they limit people's capacity for expression and complex thinking.

When group members use loaded language as part of their collective opposition to society, that language operates as part of an 'antilanguage' within a subculture (DeBernardi, 1987; Halliday, 1978: 164–165). Viewing many new religions as 'antisocieties,' members reformulate the meaning of existing words or create new words entirely, thereby expressing their resistance to and differences from mainstream society. Moreover, these linguistic reformulations help maintain the unorthodox social reality that the group has created. Thus, language functions as a method of normalization within the context of resocialization. As one of many examples from the 1970s,

the Children of God's leader, David Berg, specifically borrowed popular slogans from the women's liberation movement but inverted the meaning of the words by portraying 'revolutionary women' as ones who were sexually available and seductive (rather than independent and opposed to patriarchy) (Kent, 2001: 163–165.

Keeping in mind the role that language plays in resocialization, the logic behind a basic tenet of Scientology becomes clear. All of its books begin with the instruction that the reader should never go beyond a word that he or she does not understand. This instruction reflects the fact that Hubbard's writings are filled with new terminology, new words, new meanings for existing words, and frequent abbreviations. The system of values that these new words and meanings create is an integral part of Scientology's socialization of members into its ideology. One is reminded, however, of George Orwell's (1949: 320) observation that "telescoped words and phrases had been one of the characteristic features of political language; and it had been noticed that the tendency to use abbreviations of this kind was most marked in totalitarian countries and totalitarian organizations." Orwell made this observation in the context of discussing Newspeak and added that abbreviations are effective in the reorganization of language because they remove the full meaning and context that nonabbreviated words carry. In addition, abbreviations and shortened words suggest "a tightly-knit organization and a well-defined body of doctrine" (Orwell, 1949: 320–321).

More dramatically, Scientology's redefinition of words is also an attempt to transform society to its values by getting its definitions to replace commonplace ones. Hubbard instructed his followers that "words are redefined to mean something else to the advantage of the propagandist" and added, "[g]iven enough repetition of the redefinition, public opinion can be altered by altering the meaning of a word" (Hubbard, 1971/1991: 42). The alteration of public opinion supposedly would come about "by associating different emotions and symbols with the word than were intended" (Hubbard, 1971/1991: 42). Hubbard offered these instructions as part of his efforts to "redefine medicine, psychiatry, and psychology downward and define Dianetics and Scientology upwards" (Hubbard, 1971/1991: 43), but many ideologically driven groups that have strong social agendas attempt analogous redefinitions for their own ends. Jehovah's Witnesses, for example, use 'theocratic language' to describe their group's 'divinely inspired' organizational structure and the 'godly' actions that members undertake. This language "includes the redefinition of standard English words, the emotional charging of words, the peculiar use of metaphor in argument, and the adoption of particular mannerisms of speech" (Botting and Botting, 1984: 84).

A final consideration concerning new religions and language is that some of them eschew words for silence. Although pervasive in new religions, silence remains understudied. However, some insights into its replacement of words come from a study of 17th-century Quakerism – a religion that was 'new' in 1650s England. Quakers in this period adopted a frugality of language that reflected their desire to refrain from 'fleshly activity,' believing that the use of unnecessary language was characteristic of a carnal life. Furthermore, Quakers regarded silence as a means of realizing a closer relationship with God (Bauman, 1983: 22–23). Such sentiments reappear in some new religions, occasionally with dramatic variations. For example, members of Heaven's Gate – a group forever immortalized by their members' mass suicide in 1997 – engaged in 'tomb time,' during which they only could offer brief responses to necessary questions. Because they believed that all communication would be telepathic upon their arrival in the Kingdom of Heaven, tomb time served as a method of socialization (Balch, 1995: 155). More typical is the appearance of silence in groups that practice meditation, which involves (in various ways) attempting to still the mind and eliminate the constant flow of words that constitutes ordinary consciousness.

New Zealand: Language Situation

R Harlow, University of Waikato, Hamilton, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

New Zealand's population of just over 4 million speaks a wide range of languages, yet the appearance presented to the casual visitor and the reality of life for most New Zealanders is as monolingual as one can find anywhere. English, spoken by all but a few immigrants, is by far the dominant language of public life and of most New Zealand households. Eighty-four percent of the population is monolingual and of that proportion, 98% speak only English (Census 2001, see Statistics New Zealand, 2002). This monolingualism is seen not only in these statistics, but also in the perceptible apathy towards foreign languages in the education system.

English was introduced into New Zealand for the most part by settlers who arrived in large numbers from the 1840s. Since then, New Zealand English has developed as a distinct variety, showing some similarities with Australian English.

Since well before the arrival of English however, an Eastern Polynesian language, Māori (Maori), has been spoken in New Zealand. It was brought by voyagers from the Cook Islands and other sites in Central Polynesia some 800 to 1000 years ago (see papers in Sutton, 1994). Particularly since the 1950s, there has been very considerable language shift by the Māori population, so that it was estimated in the mid-1990s that there were only some

10 000 native speakers, almost all of whom belonged to older generations.

However, since the early 1980s there have been energetic efforts to maintain and develop the language. It is now the only *de iure* official language of New Zealand (though English is clearly so *de facto*), is the language of tuition in a substantial number of preschools (*köhanga reo* 'language nests') and schools (*kura kaupapa Māori*) and even into the secondary and tertiary levels of education. Recently, a television channel that broadcasts a high proportion of its programmes in Māori was opened. At present, it is estimated that some 160 000 people can hold a conversation in Māori (Statistics New Zealand, 2002), of whom all but 12 000 are of Māori ethnicity. Thus, only about one-quarter of the half million or so people who assert Māori ethnicity can speak their language, but the present marks a considerable improvement in the language's status over the last 20 years.

Beside these two major languages of the country, another 200 or so languages are spoken by immigrant communities, especially from Northern Europe, Asia, and the Pacific. In general, these community languages do not survive beyond the first generation of immigrants and their children, but there are exceptions such as Chinese and Greek, which are preserved vigorously within their communities.

New Zealand Lexicography

G Kennedy, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Lexicography in New Zealand since the early 19th century has reflected important relationships between English and Maori, and New Zealand English and Australian English, as well as the emergence of distinctive New Zealandisms. It has also involved the contribution of New Zealand lexicographers to the ongoing *Oxford English Dictionary (OED)* project. After Lee and Kendall (1820) produced their *Grammar and vocabulary of the language of New Zealand*, which established an orthography for Maori, and included a 100-page lexicon of Maori, the first major lexicographical project was undertaken by William Williams of the Church Missionary Society. His authoritative *Dictionary of the New Zealand language* (1844) was the first of seven editions, the most recent in 1971 reflecting the work of many scholars of Maori. Williams's dictionary was notable for being Maori-to-English only, and for excluding transliterations and other borrowings from English. Important subsequent works have included Biggs (1981), an English-to-Maori dictionary based on Williams's 6th edition; Ngata (1993), a comprehensive learners' English to Maori dictionary reflecting Maori idiom from the East Coast of the North Island; and Ryan (1995), a substantial Maori-to-English and English-to-Maori glossary of over 20 000 words from each language. An English-to-Maori and Maori-to-English dictionary of over 5000 Maori neologisms was developed by the Maori Language Commission (1996).

Austral English, compiled by Edward Morris (1898) in response to James Murray's call for contributions to the *OED* project, is seminal for the study of the English lexicon in New Zealand and Australia. Words of Maori, Aboriginal, and European settler origin were set out in a series of historically ordered citations in the *OED* format, and show the extent to which the distinctive vocabulary of the varieties of English in New Zealand and Australia had begun to emerge by the end of the 19th century. Colloquial New Zealandisms were included in New Zealand-born Eric Partridge's *Dictionary of slang and unconventional English* (1937) and in Sidney Baker's *New Zealand Slang: a dictionary of colloquialisms* (1941).

A number of New Zealanders, several of whom had been students of Ian Gordon in Wellington, established scholarly careers in lexicography. Gordon himself served for many years as a New Zealand consulting editor for Collins dictionaries. R. W. Burchfield was appointed editor of the four-volume supplement to the *OED* from 1957 to 1986. H. W. Orsman was responsible for compiling the monumental *Dictionary of New Zealand English* (1997), on historical principles, containing some 6000 headwords in the format of the *OED*. Orsman also edited the *Heinemann New Zealand Dictionary* (1979), contributed a substantial selection of New Zealand items for the *Macquarie Dictionary* and (with Elizabeth Orsman) compiled a *New Zealand Dictionary* (1994). He also contributed New Zealand material for the *OED Supplement* and for the *Australian National Dictionary* (Ramson, 1988). Turner (1966) had earlier provided an overview of distinctive characteristics of New Zealand English vocabulary in different domains of use, and Deverson (2001) surveyed the emergence of dictionaries that seek to capture this idiom.

Most recently, Bardsley (2003) has completed a study of the influence of the rural sector on the New Zealand English lexicon. Deverson (1991), Kennedy (2001), and Macalister (2003) have described the influence of Maori on New Zealand English, about six word tokens in every 1000 in New Zealand English now being of Maori origin. Names of flora and fauna and place names constitute many of these, but there are increasing borrowings from social and cultural domains. Looser (2001) has explored the lexicon of New Zealand prisons. Deverson has edited a series of New Zealand dictionaries for Oxford University Press, and with Kennedy has jointly edited the comprehensive and encyclopedic *New Zealand Oxford Dictionary* (2005).

New Zealand: Language Situation

R Harlow, University of Waikato, Hamilton, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

New Zealand's population of just over 4 million speaks a wide range of languages, yet the appearance presented to the casual visitor and the reality of life for most New Zealanders is as monolingual as one can find anywhere. English, spoken by all but a few immigrants, is by far the dominant language of public life and of most New Zealand households. Eighty-four percent of the population is monolingual and of that proportion, 98% speak only English (Census 2001, see Statistics New Zealand, 2002). This monolingualism is seen not only in these statistics, but also in the perceptible apathy towards foreign languages in the education system.

English was introduced into New Zealand for the most part by settlers who arrived in large numbers from the 1840s. Since then, New Zealand English has developed as a distinct variety, showing some similarities with Australian English.

Since well before the arrival of English however, an Eastern Polynesian language, Māori (Maori), has been spoken in New Zealand. It was brought by voyagers from the Cook Islands and other sites in Central Polynesia some 800 to 1000 years ago (see papers in Sutton, 1994). Particularly since the 1950s, there has been very considerable language shift by the Māori population, so that it was estimated in the mid-1990s that there were only some

10 000 native speakers, almost all of whom belonged to older generations.

However, since the early 1980s there have been energetic efforts to maintain and develop the language. It is now the only *de iure* official language of New Zealand (though English is clearly so *de facto*), is the language of tuition in a substantial number of preschools (*köhanga reo* 'language nests') and schools (*kura kaupapa Māori*) and even into the secondary and tertiary levels of education. Recently, a television channel that broadcasts a high proportion of its programmes in Māori was opened. At present, it is estimated that some 160 000 people can hold a conversation in Māori (Statistics New Zealand, 2002), of whom all but 12 000 are of Māori ethnicity. Thus, only about one-quarter of the half million or so people who assert Māori ethnicity can speak their language, but the present marks a considerable improvement in the language's status over the last 20 years.

Beside these two major languages of the country, another 200 or so languages are spoken by immigrant communities, especially from Northern Europe, Asia, and the Pacific. In general, these community languages do not survive beyond the first generation of immigrants and their children, but there are exceptions such as Chinese and Greek, which are preserved vigorously within their communities.

New Zealand Lexicography

G Kennedy, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Lexicography in New Zealand since the early 19th century has reflected important relationships between English and Maori, and New Zealand English and Australian English, as well as the emergence of distinctive New Zealandisms. It has also involved the contribution of New Zealand lexicographers to the ongoing *Oxford English Dictionary (OED)* project. After Lee and Kendall (1820) produced their *Grammar and vocabulary of the language of New Zealand*, which established an orthography for Maori, and included a 100-page lexicon of Maori, the first major lexicographical project was undertaken by William Williams of the Church Missionary Society. His authoritative *Dictionary of the New Zealand language* (1844) was the first of seven editions, the most recent in 1971 reflecting the work of many scholars of Maori. Williams's dictionary was notable for being Maori-to-English only, and for excluding transliterations and other borrowings from English. Important subsequent works have included Biggs (1981), an English-to-Maori dictionary based on Williams's 6th edition; Ngata (1993), a comprehensive learners' English to Maori dictionary reflecting Maori idiom from the East Coast of the North Island; and Ryan (1995), a substantial Maori-to-English and English-to-Maori glossary of over 20 000 words from each language. An English-to-Maori and Maori-to-English dictionary of over 5000 Maori neologisms was developed by the Maori Language Commission (1996).

Austral English, compiled by Edward Morris (1898) in response to James Murray's call for contributions to the *OED* project, is seminal for the study of the English lexicon in New Zealand and Australia. Words of Maori, Aboriginal, and European settler origin were set out in a series of historically ordered citations in the *OED* format, and show the extent to which the distinctive vocabulary of the varieties of English in New Zealand and Australia had begun to emerge by the end of the 19th century. Colloquial New Zealandisms were included in New Zealand-born Eric Partridge's *Dictionary of slang and unconventional English* (1937) and in Sidney Baker's *New Zealand Slang: a dictionary of colloquialisms* (1941).

Newman, Paul (b. 1937)

P J Jaggar, SOAS, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Paul Newman (born March 7, 1937, Jacksonville, Florida) is one of the preeminent (Africanist) linguists of his generation and an intellectual mentor to many of his peers and colleagues. Newman's early education was at the University of Pennsylvania, where he received his B.A. (philosophy, 1958) and M.A. (anthropology, 1961), and he was awarded his Ph.D. (linguistics, 1967) at UCLA. He has held academic positions at Yale University, Bayero University (Kano, Nigeria), and Rijksuniversiteit te Leiden (The Netherlands), and has been professor of linguistics at Indiana University, Bloomington, since 1983. In January 2002 he was appointed a distinguished professor, the university's highest academic rank. He is also the founding editor of the *Journal of African languages and linguistics*, the leading journal in the field.

Newman's first experience of Africa was as a Peace Corps volunteer in Nigeria (1961–1963); he has since returned to Nigeria numerous times to work and conduct research. In 1966, together with his fellow graduate student (and future wife) Roxana Ma Newman, he published a breakthrough paper on the Chadic language family (including Hausa), which has become the accepted point of departure for subsequent descriptive and comparative research in the field, with broader implications for the Afroasiatic phylum. With this bold and influential paper, he announced his arrival on the Hausa/Chadic/Afroasiatic stage.

Newman is a prolific scholar who has authored 16 books and monographs and more than 110 articles and reviews over the last 40 years; his key publications are all highly original but accessible works that have established his international reputation as a fearless and expansive thinker, always prepared to challenge prevailing orthodox views and notions. Although his scientific output spans a wide range of linguistic investigation, his most significant contributions have been in the area of morphophonology. His sophisticated insights regarding the phonological role of 'syllable weight' in Hausa (Newman's term) and two related languages (1972), for example, informed and influenced not only subsequent studies by Chadicists and Africanists, but also caught the wider attention of theoretical generative phonologists and typologists, placing him fairly and squarely within the general linguistic frame. Although he has introduced important concepts to the linguistic canon (e.g., 'pluractional verbs'), Newman remains an instinctive and unrepentant empiricist who prefers working with facts rather than formal theories. His crowning scientific achievement, which synthesizes his linguistic erudition and enormous knowledge of Hausa, is his landmark *The Hausa language: an encyclopedic reference grammar* (2000), the most comprehensive grammar ever written on an African language, complete with a revolutionary alphabetic ordering of topics. As an authority on linguistic fieldwork methodology, he also co-edited *Linguistic fieldwork* (2001), a collection of essays that has helped revive interest in anthropological linguistics and endangered languages. In 2002 a *Festschrift* was published in recognition of his immense contribution to our knowledge and understanding of Hausa and Chadic.

Possessed of an insatiable intellectual curiosity and desire for knowledge, Newman later turned his attention to legal studies and received a J.D. degree from Indiana University (*summa cum laude*) in May 2003. As an adjunct law professor he has taught contract law at the university's School of Law in Bloomington, in addition to undergraduate linguistics classes in 'Freedom of speech in the United States' and 'Language and law,' while continuing to teach African linguistics courses. An inveterate and tenacious fighter for liberal causes (and a jazz aficionado), in 2002 he won an age-discrimination complaint against Indiana University, helped force the local Monroe County Council to abandon prayer at its public meetings in 2004, and does pro bono work for the Indiana affiliate of the American Civil Liberties Union.

News Language

A Bell, Auckland University of Technology, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

The language of news media has always attracted the attention of linguists (particularly applied and sociolinguists) and discourse analysts. The practical and principled reasons for this interest include the accessibility of language data from the media, the significance of the media as language-producing institutions, linguistic interest in the ways media use language, and the importance of media institutions and their discourses in shaping culture, politics and social life.

Linguistic research on the media has always emphasized this last concern, focusing where issues of ideology and power are closest to the surface. It has analyzed the macro level of discourse structures rather than phonological or syntactic structures and has concentrated mainly on the 'factual' genres (particularly news) rather than fictional or advertising content (an emphasis that is shared by sociological and communications research on media).

The principal lines of contemporary research on news language were established in the 1990s, mainly under the umbrella of 'Critical Discourse Analysis'. CDA represents an outgrowth of the work of the British and Australian pioneers of Critical Linguistics, particularly Fowler and Kress, in convergence with the approaches of the British discourse analyst Fairclough and Dutch text linguist van Dijk. Van Dijk began to apply his theory and methodology of discourse analysis to media texts in the 1980s. The first general textbooks in English on media language appeared in 1991, by Fowler and by Bell, to be followed in 1995 by Fairclough's text. Boyd-Barrett (1994) provides a clear summary and even-handed assessment of the approaches of van Dijk, Fowler, and Bell.

Some form of CDA has become established as the standard approach to media texts within European linguistics, although the paradigm is less familiar in the United States. The major work reviewed here is either explicitly a form of CDA or congenial to it where its concerns overlap (Bell, 1991, 1994). CDA is more a shared perspective than a single school or a methodology. It has an explicit sociopolitical agenda, a concern to reveal the role of discourse in reproducing or challenging sociopolitical dominance. The media are a particular subject of CDA analysis because of their manifestly pivotal role as discourse-bearing institutions.

The most comprehensive work on media discourse has been undertaken by van Dijk (1988a, 1988b, 1991). Van Dijk's framework aims to integrate the production and interpretation of discourse as well as its textual analysis. His approach to news discourse was proposed as a 'new, interdisciplinary theory of news in the press' (1988b: vii). *News as discourse* (van Dijk, 1988b) appeared as a primary theoretical contribution to the analysis of news stories, supplemented by a volume of case studies, *News analysis* (1988a). These are drawn mainly from a massive sample of international news reporting and a study of racism in the European press. His 1991 book *Racism in the press* analyzes the reporting of ethnicity in a large sample of stories from British newspapers. Van Dijk's later work (e.g., 1998) extends beyond news to genres such as opinion texts and editorials.

Van Dijk's main contribution has been a framework for analyzing the discourse structure of news stories. The thematic structure of a story consists of its topics and their organization within the story. This gives the broad semantic structure. Closely parallel is the syntactic structure, which van Dijk terms 'news schemata'. News schemata are thus a syntax of news stories, the formal categories into which news can be analyzed and their relations to each other. They can be tree-diagrammed to show the discourse structure of the story. Van Dijk's analysis of newspaper stories in many languages (1988a) found few significant differences in news discourse structure. There were some differences between papers in the 'First' and 'Third' Worlds, but the greatest differences were between 'quality' and 'popular' newspapers, for instance within West Germany and the United Kingdom.

Also working within CDA, Norman Fairclough has developed an approach that draws on Halliday's functional linguistic framework, but he adds a knowledge of recent social theory that is rarely encountered in linguistics. His framework was initially developed independent of a concentration on media language, although it is no accident that many of his example analyses are of media texts, because the media – whose business is discourse – play a crucial role in shaping and purveying discourses. His book on *Media discourse* (1995) ranges more widely across the media than just the news, covering a variety of nonfictional broadcast genres. In a wider text, Fairclough (2003) lays out his

approach to CDA in general terms, including some specific news examples.

Fairclough has worked with three dimensions in discourse analysis. Text analysis concentrates on the actual language text, examining vocabulary, syntax and cohesion, and the macrolevel of text structure. Secondly, analysis of discourse practice examines how the text is produced and interpreted, and also how it is distributed, with the media as a case of complex distribution of texts from other sources. This level of analysis also looks at wider issues of orders of discourse – the characteristic discourse practices of institutions such as the media. Thirdly, analysis of social practice focuses on discourse in society, institutions, and culture and in particular on the relation of discourse to power and ideology.

Fairclough has emphasized several trends toward change in the discourses of contemporary society, particularly in the media. Marketization is the increasing use of promotional language adopted from advertising by other domains. A second trend is toward the democratization or conversationalization of discourse in the media as in other institutions – a shift to increased informality of language. Fairclough (2000) covers the discourse of the Blair government in the UK in these terms. Fairclough's is probably the most influential of the approaches to news language, with published studies by others frequently adopting aspects of his approach and methodologies in their analyses.

Bell's text *The Language of News Media* (1991) draws on the author's experience as a journalist and editor, including analysis of news stories written or edited by himself or journalistic colleagues. Three themes are central in this approach: the processes that produce media language, the notion of the news story, and the role of the media audience.

Bell stresses that news discourse is the product of multiple hands. Journalists make use of a range of spoken and written sources in writing a story. Once the story leaves the journalist's hands, it then passes through multiple editing stages before being eventually published. Bell emphasizes that the idea of the story is central to news. Journalists do not write articles, they write stories – with structure, order, viewpoint, and values. Bell (1991) examined how news stories differ from other kinds of narratives, beginning with a summary 'lead' sentence and eschewing chronological order. News values drive the way news stories are structured, and the lead sentence embodies the character of the story. News discourse is analyzed in terms developed from analysis of personal narratives and van Dijk's framework: summary (headline and lead), attribution, events, actors, setting (time, place), followup, commentary, and background. Bell has continued to work on the structure of news stories (e.g., 1995), more recently looking at how news discourse developed across the 20th century (Bell, 2003).

A fourth leading approach to news language is through the analysis of broadcast interviews, which is of interest largely because of the sociopolitical salience of the content and participants in political interviews. Since the mid–1980s a number of researchers have used Conversation Analysis to analyze broadcast interviews. The leading work is by Clayman and Heritage in the United States and by Greatbatch in the United Kingdom (e.g., Clayman, 1991; Greatbatch, 1998). Clayman and Heritage's book (2002) brings together much of the material in this area.

Useful overviews of media language research include Cotter (2001), which covers both discourse studies and more 'sociolinguistic' work focusing on the linguistics of news language in its own right below the discourse level (e.g., Bell, 1991, 2003; Biber, 2003; Jucker, 1992). The reader edited by Bell and Garrett (1998) brings together summary presentations and exemplifications of the main approaches to news discourse. Each contributor summarizes their framework and provides an illustrative analysis to show how it works. The apparatus involved in some of the approaches is formidable, and this text attempts to make them more accessible to students and other nonspecialists.

Most contemporary studies of news language claim CDA as their framework, although in many cases they work with only a small amount of the social or linguistic apparatus involved. The journal *Discourse & Society* (edited by van Dijk) is a particular forum for CDA and related work, and a significant proportion of the papers it publishes concern media discourse. These range across discrimination and stereotyping in areas such as sports reporting (Bishop and Jaworski, 2003) and coverage of ethnic minorities in Finland (Pietikäinen, 2003). Studies of 'news about the future' have been conducted by Jaworski, Fitzgerald and Morris (2003, 2004), examining how unscheduled leaks of news and the buildup to a scheduled future event are represented linguistically. The intertextuality or hybridity of media genres is the focus of Östman and Simon-Vandenbergen (2004), who brought together several studies that look at how discourse styles mix in the media.

With the growth of new media, particularly those that are based on the Internet, scholars have begun to research language use in these forms. For example, Richardson (2001) examined news and internet newsgroups, Richardson and Meinhof (1999) investigated how 24-hour channels affect news, and

Aitchison and Lewis (2003) covered a range of work on the language of new media. Nevertheless, the gaps in research on news language remain very much as identified by Bell and Garrett (1998) – there is a dearth of work on the production of news language and to a lesser extent on its reception.

Newspeak

P Chilton, University of East Anglia, Norwich, UK

© 2006 Elsevier Ltd. All rights reserved.

Newspeak

The word 'Newspeak' was introduced by George Orwell in his novel *Nineteen Eighty-Four*, which was first published in Great Britain in 1949. In that novel, Orwell represents a totalitarian society in which the ruling party is in the process of inventing a new artificial language, Newspeak. According to a definition given in an appendix to the novel, "the purpose of Newspeak was to provide a medium of expression for [a] world-view," and at the same time to "make all other modes of thought impossible."

According to Orwell's fiction, Newspeak is based on the premise that a particular 'reality' can be imposed by imposing a particular language. A number of other details are given in the novel, almost all of which are psychologically and linguistically implausible. There were three classes of Newspeak: a class required in everyday life; a class "deliberately constructed for political purposes"; and a scientific and technical class. The vocabulary of each is supposedly constructed to express only ideologically approved meanings. Thus, some words are removed entirely, new words representing new concepts are introduced, and old words are 'stripped' of unorthodox meanings. Orwell seems to have been aware of the difficulty of preventing speakers from producing new meanings, for he notes that Newspeak also eliminates "the possibility of arriving at them by indirect methods." Thus, the word *free* would have its political and philosophical sense removed and would be restricted entirely to the sense found in a sentence such as *this field is free from weeds*. Morphological processes and categories are simplified. Nouns and verbs have the same form. Thus, the noun *thought* is replaced by *think*. Semantically connected terms have similar morphology: *cut* is eliminated and replaced by the verb *knife*. Adjectives are formed by regular suffixation of nouns (*speed*, *speedful*), with a only a small set of independent adjectives (*good*, *strong*, *black*, etc.) being retained. Comparative and superlative forms are formed by regular suffixation: *good–gooder–goodest*; suppletive forms are suppressed. All adverbs are formed by the suffix *-wise*: e.g., *goodwise* replaced *well*. Antonyms are all derived by the prefix *-un*: *good–ungood*, *cold–uncold*, *person–unperson*. Other prefixes are *ante-*, *post-*, *up-*, *down-*, etc., and the intensifiers *plus-* and *doubleplus-*, giving, e.g., *pluscold* and *doubleplusungood*. The tense morphology of verbs is regularized: *think–thinked*, *steal–stealed*, etc. The number morphology of nouns is also simplified: *mans*, *lifes*, etc. The principle behind these changes or tendencies, according to the novel, is ease of pronunciation, but the major principles are evidently agglutination and one-to-one correspondence of meaning and morpheme.

Compounding and abbreviation are supposed to be additional characteristics of Newspeak. For example, *goodthink* replaces *orthodoxy* and has the forms *goodthinked*, *goodthinkful*, *goodthinkwise*, *goodthinker*, *crimethink*. These forms are modified (in the political version of Newspeak) by apocope and 'euphony' principles: *Thinkpol* (Thought Police), *Minitrue* (Ministry of Truth)–*Minitruthful*, *Minipax–Minipeaceful*, *Miniluv–Minilovely*.

Newspeak meanings are supposed to be unique to the system and intelligible only to its speakers. Thus, *oldthinkers unbellyfeel Ingsoc* had a language-specific and untranslatable meaning, according to Orwell. The Newspeak sentence *all mans are equal* could only mean 'equal in size' (*see* **Meaning: Overview of Philosophical Theories**). The 'Declaration of the Rights of Man' is untranslatable. Newspeak meanings are also unique in the sense that there is supposedly no ambiguity, polysemy, or connotation: "Every concept that can ever be needed will be expressed in exactly *one* word, with its meaning rigidly defined and all its subsidiary meanings rubbed out." But Newspeak also aims to reduce the number of words in its lexicon and to achieve this end some meanings are simply eliminated. (Orwell, or his novel, does not tell us how.) Thus, the meanings covered by the English words *honour*, *justice*, *morality*, *internationalism*, *democracy*, *science*, and *religion* cease to exist along with the words themselves. They are replaced, we are told, by semantically vague words, such as *crimethink*, *oldthink*, *goodsex*, and *sexcrime*.

The meanings of all lexical items in Newspeak are ideological; many are euphemisms and some terms are supposed to invert the evaluative associations of 'oldthink' terms: *joycamp* (forced-labor camp), *Minipax* (Ministry of War). This principle is followed in the sentences of party propaganda: "Ignorance is Strength," "War is Peace," "Slavery is Freedom." Since the political vocabulary of Newspeak is an elite variety, some words represent the structures of society with cynical literalness, e.g., *prolefeed* (cheap entertainment for the proletariat) (*see* **Taboo, Euphemism, and Political Correctness**).

Names of organizations, countries, institutions and the like are abbreviated: *Recdep* (Records Department), *Ficdep* (Fiction Department), *Teledep*

(Tele-programmes Department), *Minitrue*, and *Ingsoc* (English Socialism). Orwell presents these fictional forms as a continuation of the real historical tendency to produce forms such as *Nazi*, *Gestapo*, *Comintern*, and *Agitprop*. According to Orwell, the reason for these forms is not just economy of effort, but the intention to limit and control associations. He also claims that the syllabic structure of Newspeak words (always one or two syllables), together with a regular word-stress pattern, has not only a phonological function (to permit rapid speech) (*see* **Intonation**), but also a cognitive function: to reduce conscious reflection. The use of such words is termed, non-pejoratively, *duckspeak*.

Orwell's Newspeak is part of a tradition. Utopian fictions often portray idealized languages; *Nineteen Eighty-Four* turns the idea on its head. Speculation about language from the 17th century rationalists to Wittgenstein raised suspicions about natural language and proposed ideal rational systems that would mirror the world directly. Some writers, such as Jonathan Swift, satirized the idea; some writers, such as C. K. Ogden in the 20th century, popularized it. Orwell, appalled by contemporary totalitarianism, gave it a contemporary political twist.

Ngan'gi

N Reid, University of New England, Armidale, Australia

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Ngan'gi (Ngan'gikurunggurr) is an Australian Aboriginal language spoken in the Daly area several hundred kilometers to the southwest of Darwin. The language now has two significant dialectal variations: Ngan'gikurunggurr has about 150 speakers, and Ngen'giwumirri has about 50. These two dialects share about 89% of vocabulary, have nearly identical systems of complex verb morphology, and are mutually intelligible. For our purposes, we can treat them as a single language and give it the label 'Ngan'gi,' although speakers are careful to distinguish between them as characterizing two separate groups with distinct social identities. Ngan'gi is spoken predominantly in the townships of Nauiyu (formerly Daly River) and Peppimenarti, and the outstations that those two towns supply. Most people who speak Ngan'gi fluently are aged more than 50 years, and the children of Ngan'gi speakers now mostly learn Kriol as their first language. With this number and age profile of speakers, Ngan'gi is classified as a 'threatened' language, under real danger of extinction within a few decades.

Classification

The first classification of Daly region languages (Tryon, 1974) paired Ngan'gikurunggur and Ngen'giwumirri as constituting the Tyemeri branch of the 'Daly Family,' with neither related to Murrinh-Patha, the neighboring language to the west. This understanding, of either no relationship or at best a very distant one, between Ngan'gi and Murrinh-Patha, was based on the lexical data; Ngan'gi and Murrinh-patha have at most an 11% shared vocabulary density.

Present research is however overturning this view. Green (2003) has made a compelling case for Ngan'gi and Murrinh-patha making up a genetic subgroup now labeled 'Southern Daly.' The case is based primarily on formal correspondences in the core morphological sequences of finite verbs. Green argues that these sequences match too closely in their complexities and irregularities to have plausibly come about through anything other than a shared genetic legacy; he demonstrates through reconstruction of finite verb paradigms that they are systematically derivable from an innovative common parent. The intriguing question, of how related neighboring languages have come to share as little as 11% lexical cognacy, remains unanswered.

Instead of a single 'Daly Family,' there now appears to be five separate Australian subgroups in the Daly

(Tele-programmes Department), *Minitrue*, and *Ingsoc* (English Socialism). Orwell presents these fictional forms as a continuation of the real historical tendency to produce forms such as *Nazi*, *Gestapo*, *Comintern*, and *Agitprop*. According to Orwell, the reason for these forms is not just economy of effort, but the intention to limit and control associations. He also claims that the syllabic structure of Newspeak words (always one or two syllables), together with a regular word-stress pattern, has not only a phonological function (to permit rapid speech) (*see* **Intonation**), but also a cognitive function: to reduce conscious reflection. The use of such words is termed, non-pejoratively, *duckspeak*.

Orwell's Newspeak is part of a tradition. Utopian fictions often portray idealized languages; *Nineteen Eighty-Four* turns the idea on its head. Speculation about language from the 17th century rationalists to Wittgenstein raised suspicions about natural language and proposed ideal rational systems that would mirror the world directly. Some writers, such as Jonathan Swift, satirized the idea; some writers, such as C. K. Ogden in the 20th century, popularized it. Orwell, appalled by contemporary totalitarianism, gave it a contemporary political twist.

Introduction

Ngan'gi (Ngan'gikurunggurr) is an Australian Aboriginal language spoken in the Daly area several hundred kilometers to the southwest of Darwin. The language now has two significant dialectal variations: Ngan'gikurunggurr has about 150 speakers, and Ngen'giwumirri has about 50. These two dialects share about 89% of vocabulary, have nearly identical systems of complex verb morphology, and are mutually intelligible. For our purposes, we can treat them as a single language and give it the label 'Ngan'gi,' although speakers are careful to distinguish between them as characterizing two separate groups with distinct social identities. Ngan'gi is spoken predominantly in the townships of Nauiyu (formerly Daly River) and Peppimenarti, and the outstations that those two towns supply. Most people who speak Ngan'gi fluently are aged more than 50 years, and the children of Ngan'gi speakers now mostly learn Kriol as their first language. With this number and age profile of speakers, Ngan'gi is classified as a 'threatened' language, under real danger of extinction within a few decades.

Classification

The first classification of Daly region languages (Tryon, 1974) paired Ngan'gikurunggur and Ngen'giwumirri as constituting the Tyemeri branch of the 'Daly Family,' with neither related to Murrinh-Patha, the neighboring language to the west. This understanding, of either no relationship or at best a very distant one, between Ngan'gi and Murrinh-Patha, was based on the lexical data; Ngan'gi and Murrinh-patha have at most an 11% shared vocabulary density.

Present research is however overturning this view. Green (2003) has made a compelling case for Ngan'gi and Murrinh-patha making up a genetic subgroup now labeled 'Southern Daly.' The case is based primarily on formal correspondences in the core morphological sequences of finite verbs. Green argues that these sequences match too closely in their complexities and irregularities to have plausibly come about through anything other than a shared genetic legacy; he demonstrates through reconstruction of finite verb paradigms that they are systematically derivable from an innovative common parent. The intriguing question, of how related neighboring languages have come to share as little as 11% lexical cognacy, remains unanswered.

Instead of a single 'Daly Family,' there now appears to be five separate Australian subgroups in the Daly

Table 1 Genetic subgroups in the Daly River region

Subgroup	*Principal language varieties*
Anson Bay	Batytyamalh (aka Wadyiginy) (Wadjiginy) Kenderramalh (aka PunguPungu)
Northern Daly	MalakMalak (Mullúkm̀ulluk), Tyeraty, Kuwema (Tyaraity)
Eastern Daly	Matngele Kamu
Western Daly	Marrithiyel (Marithiel), Marrisyefin, Marri Ammu Marringarr (Maringarr), Mati Ge Marramaninydyi (Marimanindji) Marranunggu (aka Warrgat) (Maranunggu), Emmi, Menhthe
Southern Daly	Murrinh-Patha Ngan'gikurunggurr (Nangikurrunggurr), Ngen'giwumirri

region that cannot convincingly be related together as a single genetic unit (Table 1) (Green, 2003). Those similarities that Tryon took to be diagnostic of the 'Daly Family' are better accounted for either diffusionally or as genetically inherited features shared with a wide range of northern Australian languages.

Areal Features

Like the majority of languages spoken in Australia's central far north, Ngan'gi is of the polysynthetic (*see* **Polysynthetic Language: Central Siberian Yupik**) structural type, and is categorized within Australianist typology as belonging in the non–Pama-Nyungan and prefixing groups. It has complex verbal structures built up through the addition of strings of prefixes and suffixes to lexical roots. Some of the affixes are suppletive in form and many are portmanteau in nature, simultaneously encoding a number of grammatical categories. A large complex verb might have up to a dozen constituent morphemes and correspond in meaning to a whole English sentence. The most distinctive grammatical features of Ngan'gi are its extensive pronominal indexing, a set of 31 classifying verbs, 4 number categories for pronouns, a system of 16 noun classes, and a 3-way stop/fricative contrast.

Pronominal Indexing

Verbs obligatorily index core participants such as 'subject' (***I*** *saw you*) and 'object' (*I saw* ***you***) by bound pronominal prefixes. Most languages additionally allow for the verbal cross-referencing of other kinds of participants, such as 'goals' (*I told* ***her*** *the news*), 'benefactives' (*I cooked it* ***for her***) and 'adversatives' (*My wife ran away* ***on me***). Pronominal indexing is shown in (1), where subject, object, and adversative arguments are indexed on the one complex verb.

(1) Danginy-nyi-fime-ngidde-wurru.
3sg.S.Poke.Perf-2sg.O-give-1sg.Adv-bad
'She gave it away to you against my wishes.'

Some grammatical categories, such as person, number, and tense, can be marked discontinuously via different affixes at different points in the verb. This marking is illustrated for subject number in (2), which stacks plural, dual, and trial affixes.

(2) Ngarrgu-nime nge-rr-beny-gu-da-nime.
1exdlPRO-trial 1.S-nsg.S-Bash.Perf-dl.S-hit-tr.S
'We (trial exclusive) hit it.'

Verbal Classification

Many languages of Australia's central far north share the characteristic of forming their verbs with not one, but rather two, root-like elements. This two-part structure typically involves the pairing of a relatively inert root (or coverb), which provides the main lexical information for the verb, with a root that hosts the core grammatical affixes (or finite verb). Coverbs form an open class, while finite verbs constitute a small closed class – Ngan'gi has 31 of these. This two-part verbal structure is thought to be an ancient diffusional feature. While in some languages of Australia's north the finite verbs have synchronically no clear semantic value, in the Southern Daly languages, it functions as a classifier of the verbal action. Verbal classification may simply involve specifying the relative orientation of the subject, as with the intransitive posture classifiers in (3) and (4).

(3) Peke dini-fifi-tye.
tobacco 3sgSit.IMP-smoke-Past
'He was sitting smoking.'

(4) Peke wirringe-fifi-tye.
tobacco 3sg.S.Sit.IMP-smoke-Past
'He was standing smoking.'

Other verbal classifiers are concerned with how objects are handled or manipulated, as illustrated by the transitive classifiers in (5) and (6). In (5), the finite verb *Hands* functions to conceptualize the action as performed within the grasp of the fingers. Contrast with (6), in which the replacement of *Hands* with *Poke* achieves a different schematic conceptualization, this time of the action as performed at the end of an elongated instrument.

(5) Ngeriny-fityi peke.
1sg.S.Hands.Perf-roll tobacco
'I rolled a cigarette' (in my hands).

(6) Ngariny-fityi screwdriver-ninggi.
1sg.S.Poke.Perf-roll screwdriver-INSTR
'I screwed it up with a screwdriver.' (I rolled it at the end of a long thin instrument).

Table 2 Ngan'gi freeform pronouns

Number	*1st inclusive*	*1st exclusive*	*2nd person*	*3rd person*
Singular		*ngayi*	*nyinyi*	*nem* (male) *ngayim* (female)
Dual	*nayin*	*ngagarri*	*nagarri*	*wirrike*
Trial	*nayin nime*	*ngagarri nime*	*nagarri nime*	*wirrike nime*
Plural	*nayin nime*	*ngagurr*	*nagurr*	*wirrim*

When compared to the other languages of the Daly, and to northern Australia generally, the classifying verb structures of Ngan'gi reveal two aberrant features. First, they exhibit a tight morphophonological binding between coverb and the inflected finite root. Second, they show an innovative ordering, placing the coverb after the inflected finite root rather than preposed to it. Reid (2003) argued that these shared features result from recent diffusion rather than a shared genetic legacy, demonstrating how the Southern Daly languages Ngan'gikurunggurr and Ngen'giwumirri have acquired them only within the last hundred years.

Free Pronouns

The Daly languages have freeform pronoun systems that are complex by virtue of grammaticizing multiple nonsingular number categories. Some languages, including Ngan'gi, have singular/dual/trial/plural systems, while others have singular/dual/paucal/plural systems. As can be seen from Table 2, Ngan'gi has a slightly nonsymmetrical system where the trial/plural contrast is neutralized in 1st inclusive.

Nominal Classification

All the Daly languages have at least a few generic nouns, such as 'meat,' 'vegetable food,' and 'fire,' which are regularly placed in front of specific nouns to encode salient cultural categories. In some Daly languages, this encoding has become extended into a system in which the category membership of all entities is obligatorily encoded by one of around a dozen NP initial generic nouns. In Ngan'gi, such generic-specific constructions have undergone even further grammaticalization, displaying agreement phenomena and reduction of the independent generic to bound forms. Sometimes, agreement is marked by bound forms attached to nouns as well as modifiers such as adjectives or demonstratives. In other cases, noun class assignment is marked by freeform generics that precede specific nouns and also precede the modifiers. Each of these types is demonstrated in (7) and (8).

Table 3 Ngan'gi phonemic inventory consonants

Consonant type	*Bilabial*	*Alveolar*	*Palatal*	*Velar*
Voiceless stop	p	t	ty	k
Voiced stop	b	d		
Fricative	f	s	sy	g
Nasal	m	n	ny	ng
Lateral		l		
Approximant		r		
Trill		rr		
Glide	w		y	

(7) a-tyalmerr a-kerre a-kinyi
animal-barramundi animal-big animal-this
'this big barramundi fish'

(8) syiri magulfu syiri marrgu
weapon fighting.stick weapon new
'a new fighting stick'

Noun class phenomena in Daly languages have proved theoretically interesting by providing a perspective on the historical development of class markers from freeform nouns to proclitics to prefixes. They have also contributed to theorizing about the process by which agreement phenomenon develop (Reid, 1997) and to considerations of the nature of the distinction between noun class and noun classifying systems (Green, 1997).

Phonology

Australian languages generally lack phonemic fricatives and typically have just a single series of stop. The Daly region shows a significant departure from this pattern, with all languages except Anson Bay showing at least some phonemic voicing contrast. Ngan'gi has both a partial stop contrast, and phonemic fricatives, yielding a 3-way obstruent contrast between a voiced stop, voiceless stop and fricative for the bilabials and alveolars. The phonemes of Ngan'gi, showing the atypical obstruent set in an

The República de Nicaragua has recognized its citizens' right to develop and use local languages, and it has been especially active in reviving and promoting its minority languages. Spanish is the dominant household language throughout all but the Caribbean coastal areas, and its dominance is unchallenged in the urbanized departments of the highlands and the Pacific coast. The language of national government and the medium of school instruction, Spanish is also the country-wide lingua franca. However, eastern parts of the country, which historically have been more closely linked to British and U.S. commercial interests, have maintained a significant indigenous presence. Recently, these areas have been reorganized into the RAAN (Región Autónomo del Atlántico Norte) and the RAAS (Región Autónomo del Atlántico Sur), and Miskitu, Sumo, and English have been declared official languages of these *departamentos*. According to one government survey, more than 20% of the RAAN and RAAS residents use mother tongues other than Spanish, as compared to less than 3% for the republic as a whole.

Miskitu (Mískito, Mísquito) speakers inhabit the Atlantic coast and lowlands, especially from the Honduran border on the river Coco south to the Laguna de Perlas. A Misumalpan language spoken on both sides of the international border, Miskitu

The República de Nicaragua has recognized its citizens' right to develop and use local languages, and it has been especially active in reviving and promoting its minority languages. Spanish is the dominant household language throughout all but the Caribbean coastal areas, and its dominance is unchallenged in the urbanized departments of the highlands and the Pacific coast. The language of national government and the medium of school instruction, Spanish is also the country-wide lingua franca. However, eastern parts of the country, which historically have been more closely linked to British and U.S. commercial interests, have maintained a significant indigenous presence. Recently, these areas have been reorganized into the RAAN (Región Autónomo del Atlántico Norte) and the RAAS (Región Autónomo del Atlántico Sur), and Miskitu, Sumo, and English have been declared official languages of these *departamentos*. According to one government survey, more than 20% of the RAAN and RAAS residents use mother tongues other than Spanish, as compared to less than 3% for the republic as a whole.

Miskitu (Mískito, Mísquito) speakers inhabit the Atlantic coast and lowlands, especially from the Honduran border on the river Coco south to the Laguna de Perlas. A Misumalpan language spoken on both sides of the international border, Miskitu

has long been written by the Moravian Church, the most important religious organization in the Miskitu community, and it is the language of worship in the Miskitu speech area. Good dictionaries, a reference grammar, bibles, hymnals, and other religious materials are available, and Miskitu language literacy is widespread. The national government has encouraged the maintenance of Miskitu and has facilitated the publication of dictionaries and other literacy materials, especially for the Wangki dialect. Miskitu language courses are offered in Bilwi, the capital of RAAN. With well over 70 000 speakers, Miskitu is, along with Spanish, a lingua franca throughout the Miskitu area. There are regular radio broadcasts in Miskitu.

Up river from the areas of Miskitu dominance live two-thirds of Nicaragua's 6000 speakers of Sumo (Sumu, Sumo Tawahka), another Misumalpan language. This ethnic group prefers the collective name Mayangna, which is now used in government reports, though its three Nicaraguan dialects are known as Tuahka (Twahka, Nicaraguan Tawahka), Panamahka, and Ulwa. Though they continue to resist complete acculturation by maintaining their own language, they are highly multilingual, preferring to speak Miskitu, Creole English, or Spanish, a fact that has contributed to counting errors in language surveys. The greatest concentration of speakers is in Bonanza. Especially endangered, the southern dialect Ulwa is not readily intelligible to speakers of the northern dialects Tuahka and Panamahka, and it has received separate recognition by the government, even though it has but a few hundred older speakers, nearly all in Karawala near the mouth of the Río Grande de Matagalpa.

A language rescue project was begun in 1984 for the Chibchan language Rama, which had only 31 known speakers in 1986, living in Cane Creek, Monkey Point, Wiring Cay, and Pataste. Although most ethnic Rama speak Spanish and Creole English, a basic Rama language course was developed for the elementary school on Rama Cay to teach this heritage language to the ethnic Rama children, and this seems to be the only community where Rama is now actively spoken.

Nicaragua reports over 20 000 speakers of Western Caribbean Creole English, found throughout the RAAN and RAAS, but most dominant in Rama Cay and the area around Bluefields. Even though these Creole speakers often consider English their standard target, they do not normally identify with the United States or Great Britain. Many Creole speakers are ethnic Mayangna or ethnic Rama who have forsaken their ethnic language. A small population of ethnic Garifuna live in Orinoco and other villages of Laguna de Perlas, and they too are reported to now speak Creole English.

Over 3000 deaf use a regional sign language, Idioma de Señas de Nicaragua (Nicaraguan Sign Language), which is distinct from American Sign Language and other well-known sign languages.

Nicknames

P Hanks, Berlin-Brandenburg Academy of Sciences, Berlin, Germany and Brandeis University, Waltham, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Social Origin and Function of Nicknames

A nickname is an 'eke name' (from Middle English *eke* 'also'), an additional name borne in addition to a person's proper or official name. According to Morgan *et al.* (1979), nicknames typically originate "in the autonomous social world that children construct independently of adult influences. Children invent nicknames spontaneously, using language creatively in accordance with a logic which is not laid down from outside." It should be noted, however, that not only children coin nicknames: Adults coin nicknames with almost equal readiness, Abel (2004) gives some examples. The linguistic register of a nickname is always informal. Nicknames are typically ephemeral and, as with certain kinds of slang, confined to quite small in-groups. To know who *Sweaty Nine Fingers* was, you would have to have attended a particular British school in the 1950s, where the slang term *sweaty* meant 'prone to sudden outbursts of anger (*sweats*)' and one such individual had, congenitally, fewer fingers than the norm. The total language community using this term was thus confined to around 300 people for a period of less than 10 years.

Nevertheless, some nicknames – those bestowed on public figures – transcend the in-group and can even become established as a permanent part of the historical record of a culture. Yet, even though the phenomenon of nicknames seems to be universal, not every public figure receives a nickname. Nicknames are based on a salient distinctive character or characteristic. The Roman Emperor Gaius Germanicus is known to history by his nickname *Caligula,* which means, roughly 'little boots.' Napoleon accumulated nicknames throughout his career – some hostile, some admiring, some respectful, some demeaning (depending on who coined them): *Le Petit Caporal, The Man of Destiny, The Corsican Ogre,* and *Boney* are just some of them. By the end of her career, the British politician Margaret Thatcher had received almost as many nicknames as Napoleon: *The Iron Lady, Attila the Hen, The Leaderene, Tina* (an acronym based on her catch phrase "There is no alternative"), *Milk Snatcher* (a rhyming nickname alluding to her policy of withdrawing government support for free milk for schoolchildren), among others. A politician who does not receive a nickname is generally a rather dull and colorless individual. By contrast, it is unusual for civil servants and bankers to receive nicknames, at any rate outside their immediate circle, although a recent governor of the Bank of England, Sir Edward George, received the nickname *Steady Eddie*. This was not only a tribute to his reliable judgement and calming influence, but also an indication that he had achieved an unusually high public profile.

Sports personalities are particularly prone to receiving nicknames. The English writer William Hazlitt records attending a prize fight in 1822 involving an individual named *The Gas Man* – another prize fighter of the period was known as *The Game Chicken* – whereas in more recent times, such nicknames as *The Brown Bomber* (Joe Louis) and *The Louisville Lip* (Muhammad Ali) spring to mind. Baseball players, footballers, and cricketers are nicknamed equally often.

Even when an unpleasant characteristic is singled out as a basis for a nickname, the effect is normally humorous, rather than hostile. The 'official' full form of a person's name (e.g., 'Mr Francis Leverett Smith') is considered cold and unfriendly in many cultures and in many places is mainly reserved for bureaucratic transactions and reprimands. In other circumstances, it can be taken as an indicator of high social status. In both cases, the effect of using the formal form of a person's name is to distance the person referred to from the speaker's social interactions. In contrast, the effect of a nickname – even a cruel, offensive, and obscene nickname – can often be to weaken the isolating effect of an offensive remark and to promote social interaction. A child with problems of personal hygiene is called *Sewer* or *Smelly*, a plump child is called *Fatty*, a child with a birthmark is called *Strawberry.* This may be cruel; yet, as a general rule, no offense is intended. As one child in Morgan's survey remarked, "She's called *Fleabag*, but she's nice and she ain't got no fleas" (Morgan *et al.,* 1979). In this case, the origins of the surname turned out to be anecdotal. It cannot be denied that such nicknames, drawing attention to a sensitive point, can wreak havoc on delicate sensibilities, yet it might also be argued that such a frank, socially interactive, and often humorous acknowledgement of salient characteristics is socially healthier than mealy-mouthed, humorless political correctness. Placing taboos on offensive terms merely serves to empower them.

Not only people but also institutions (the BBC – *The Beeb, Auntie*), companies (IBM – *Big Blue*), cities (New York – *The Big Apple*, Edinburgh – *Auld Reekie* 'Old Smokey'), and locations (the

high-technology computer research region south of San Francisco – *Silicon Valley*, the fundamentalist Christian southern states of the United States – *Jesusland*) may receive nicknames. Nicknames are sometimes exploited to form other nicknames, so that for example when the computing research industry began to become established in the cities of Cape Cod, it was nicknamed *Silicon Sandbar,* a reference to the better known *Silicon Valley.*

Nicknames are probably found in all languages. For example, the following Arabic nicknames are mentioned in Morgan *et al*. (1979): *El A'raj* 'the lame one,' *El Abufas* 'the smelly one,' *El Abushenab* 'the mustachioed one' (a tough guy), and *El Mawsou'a* 'the encyclopedia' (a know-it-all).

Nicknames and Hypocoristics

People love to play with words, and this is also true of names. People alter the forms of names in their language, creating hypocoristic forms or pet forms, which have similar properties to those of nicknames – in particular, informal register and a socially integrative function. However, whereas nicknames are independent formations, hypocoristics are altered forms of the surname or forename.

The inventory of conventional hypocoristic suffixes or processes in most languages is quite small, but is generally supplemented by occasional rare or one-off formations. In present-day English, *-y* is the most common hypocoristic suffix, added to the first syllable of forenames and surnames alike, as in *Billy, Johnny, Jenny, Jilly, Smithy, Jonesy.* In Middle English and early Modern English, *-kin* was commonly added to male forenames, as in *Peterkin, Hankin, Wilkin*. The process of forming a hypocoristic by shortening a name and adding *-l* was well established by Shakespeare's day, as in *Hal* for Henry. This is still an active process in present-day English, as in *Del* for Derek and *Tel* for Terry. Reduplication is also common, as in *Lulu* for Louise and *Jo-Jo* for Joseph or Josephine.

In all European languages, but especially in the Slavic languages and Italian, nouns often receive a hypocoristic suffix (pet form, diminutive). In Slavic languages, this is quite normally done with common nouns and equally so with names, so that for example the Czech word (and surname) *dvořák* 'freeholder' or 'landowner' is more often than not used in the hypocoristic form *dvořáček*, and Polish *bednarz* 'cooper' is generally used in the hypocoristic form *bednarczyk*. Czechs with the forename *Bohuslav* are often addressed and referred to by the hypocoristic form *Boček*. Russians called *Anastasia* receive various pet names; for example, *Nastasia, Nastya, Nastenka*. Altered forms are sometimes surprising. English *Will* is obviously enough a shortening of *William*, but where did the *B-* come from in the equally common hypocoristic form *Bill*? This form is first recorded in the 17th century in Ireland, where it seems likely that the *B-* is a hypercorrection, caused by a mistaken association with Gaelic words and names beginning with *B-*, the lenited form of which begins with *Bh-*, pronounced as /w/ in some dialects.

Many European family names are derived from hypocoristic forms of given names. In Italy in particular, this was a general pattern, sometimes accompanied by so much alteration or truncation that the original given name is quite unrecognizable. For example, *Pucci* is derived from a hypocoristic form of either of two given names (*Filippo* or *Iacopo*), even though it shares only one letter with the source name. An Italian hypocoristic may receive a second hypocoristic suffix, resulting in such forms as *Puccetti, Puccini,* and *Pucciarelli,* and even a third suffix, as in *Puccinelli.*

Typology of Nicknames

There is sometimes interaction between vocabulary words and nicknames. For example, the English vocabulary word *doll* (denoting a child's toy in the form of a miniature child) originated as a hypocoristic shortening of the female personal name *Dorothy*, as in the case of Shakespeare's *Doll Tearsheet*. Subsequently, the vocabulary word came to be used as an appellative for any young woman (as in "Hey, Doll, where's my burger?"). With the addition of a further hypocoristic marker *-y* (*Dolly*), it is both used as an appellative and has passed back into the general vocabulary as a term for a young woman with a superficially sexually attractive appearance (a *dolly bird*).

The main types of nicknames may be classified as follows:

- Reference to physical appearance. Examples: *Fatty, Twiggy* (a thin person), *Beaky* (someone with a large nose), *Dumbo* (large ears, from the cartoon elephant in a 1941 Disney film of this name), *Ginger, Copperknob* (red hair), *Four-eyes* (someone with glasses)
- Imputation (often unfairly) of an unpleasant characteristic. Examples: *Sewage, Stinker Hargreaves, Slimy Jones*
- Imputation of other characteristics, often satirically. Examples: *Brainbox Henderson*, *Gorgeous George*
- Behavior. "A child who used to bite in playground scuffles acquired the nickname *Tiger.* One who did

messy work became *Smudge*" (Morgan *et al.*, 1979: 40).

- Supposed resemblance to an animal. Examples: *Piggy, Frog, Toad, Fish; Animal* (in the sense 'big, strong, and stupid')
- Cultural references. Examples: *Dalek,* 'an unpopular child with a monotonous voice' (from the destructive robots in the long-running British science-fiction TV series *Dr Who*, noted for their monotonously repeated catch phrase, "Exterminate them! Exterminate them!"); *Goldilocks* (a blond boy or blonde girl); *Saffy* (a solemn young woman, from a character in the British comedy TV series *Absolutely Fabulous*), *Speedy Gonzalez* (an American cartoon film character)
- Punning reference to a job or social function. Examples: *Haversack* (a foreman, "because he's always on my back"); *Balloon* (because he had a catch phrase, "Don't let me down"); *The Bishop* (the presenter of a religious TV program)
- Pun on surname. Examples: *Long bum* and *Ramsbum* for people with the surname *Longbottom* and *Ramsbottom* (disregarding the etymological fact that the 'bottom' in question has nothing to do with the human anatomy, but refers in fact to a geographical feature – the bottom of a valley)
- Rhyming and assonance. Examples: *Beef* for someone with the forename *Keith*, *Bracket* for the surname *Hackett*
- Survival of babytalk. Example: *Ellie,* from *Eletant,* from *elephant*.

Finally, some nicknames seem to have been coined arbitrarily, or rather the reason for their origin is lost (e.g., *Biff, Dibby*), whereas in other cases the origin is anecdotal, though the circumstances may be very uncertain. The jazz musician Charlie Parker (1920–1955) was universally known as *Bird*, a shortening of *Yardbird*. It is said, with uncertain reliability, that this was a reference to his fondness for fried chicken, illustrated by his proposal, after running over a stray chicken in the road on the way to a gig, that the band should pick it up and take it with them, so that they could cook it for dinner.

Conventional Nicknames

Some nicknames are conventionally associated with particular surnames. Examples include *Dusty Miller, Chalky White, Nobby Clark*, and *Spud Murphy*. Anyone who has ever visited a traditional flour mill will know immediately why the occupational surname Miller attracted the nickname *Dusty*. For those who recall from their schooldays teachers using white chalk on a blackboard, the association of *Chalky* and White is equally obvious. It is less obvious why the surname Clark should have attracted the conventional nickname *Nobby*. *Spud Murphy* clearly owes its origin to the days when potatoes were the subsistence diet of the poorer inhabitants of rural districts of Ireland. But then why only Murphy? Why not *Spud Kelly* or *Spud Cullinane*? Even here, linguistic arbitrariness seems secure.

Nicknames as Sources of Surnames

A large class of European surnames originated as nicknames. Exemplars from all the categories of nicknames described above are also found as surnames. Particularly common are terms denoting animals and birds, such as *Fox, Hawk,* and *Lamb,* generally with reference to characteristics conventionally imputed to the creatures in question. In addition, the following classes may be mentioned.

- Occupational nicknames: English *Copestick* 'cut the stick' (a woodcutter), German *Knaack* 'bone' (a butcher), and French *Painchaud* 'hot bread' (a baker)
- Dress habits: Italian *Fazzolari*, which most probably originated as a nickname for someone who habitually wore a *Fazzolo*, a kerchief
- Speech habits English *Goody* 'good day,' and Italian *Addio* 'farewell.'

Nida, Eugene Albert (b. 1914)

F Kerleroux, Université de Paris X Nanterre, Nanterre, France

© 2006 Elsevier Ltd. All rights reserved.

Eugene Nida was born in 1914 at Oklahoma City, Oklahoma, in the United States. This linguist is known worldwide to most students of linguistics and to most teachers and researchers who have used his *Morphology, a descriptive analysis of words* (1946b), which involves theoretical analyses, practical exercises with and without answers, and concrete advice for fieldwork. This handbook contributed to the instruction of generations of linguists, thanks to its abundant empirical data (problems are taken from 49 languages, from Arabic to Zoque) and to the meticulous precision in the structuralist analysis of morphemes where the various stages are differentiated, from their identification and their classification into types to their distribution and elaboration as structural classes.

In his handbook, Nida provided definitions and demonstrations of the structuralist leaders of the period, L. Bloomfield and E. Sapir, together with incisive discussions of contributions from his contemporaries R. S. Wells, B. Bloch, and Z. Harris. During this period, two of his papers published in *Language* (1948a,b) testify to the methods and theory of American structuralism.

However, Nida's long career and many publications could have remained little known or poorly understood by the international linguistic community, since he devoted himself very early and entirely to the translation of a single corpus, the Bible (primarily the New Testament). In 1946 he published simultaneously his *Bible translating* and *Morphology, a descriptive analysis of words*.

He was one of the directors of the Summer Institute of Linguistics, founded in 1934 in Mexico, a humanitarian and missionary agency whose aim was to provide a basic linguistic education whose beneficiaries would be competent in describing the languages of minority populations and in establishing a writing system for each so that the New Testament could be read in more than 1000 languages. In 1943, during World War II, the American Bible Society was founded, and by 1947 the United Bible Society had 30 member states. Nida contributed to the translation of the Scriptures into many more languages in the last half century than had been done during the entire Christian era, making 200 official trips in 40 years. He was a consultant for the United Bible Society from 1947 to 1990 and has been a consultant for the American Bible Society since 1984.

In his latest book, entitled *Fascinated by languages* (2003), he characterizes his professional activity and choice to lecture as that of "an eclectic and a pragmatic," recalling that he organized sessions in translation in more than 90 countries and that he has published, alone or in collaboration, 13 handbooks on translation applied directly at various Biblical texts, from the *Gospel of John* in 1961 to Paul's *Letter to the Ephesians* in 1983. He explicitly links his long career to two childhood experiences as a reader of the revue *Scientific American*, which created in him a passion for the diversity of forms, and of *Genesis*. Both of these inspired him profoundly and guided him in his twofold university education: a B.A. from the University of California, Los Angeles in 1936, an M.A. in patristics from the University of Southern Carolina in 1939, and a Ph.D. in linguistics from the University of Michigan in 1943.

His principal aim has always been "to see through and beyond the words to the meaning of the text." As shown by his simultaneous publication of *Bible translating* and *Morphology: the descriptive analysis of words* in 1946, one text, the Bible, was for him the only text.

Nida has belonged to numerous learned societies that reflect his varied interests, including the American Anthropological Association, the Linguistic Society of Canada and the United States, the American Association for Applied Linguistics, and the Society of Biblical Literature, as well as the Linguistic Society of America (of which he was president in 1968) and the Society for Textual Scholarship (president, 1987–1988).

Niger: Language Situation

H E Wolff, University of Leipzig, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Niger covers a landlocked territory of 1.27 million km^2 in the semiarid and arid zones of the southern Sahara, bordering on Nigeria, Burkina Faso, Mali, Algeria, Libya, and Chad. The population in 2001 was approximately 11 million. A narrow southern zone in the valley of the river Niger and along the border to Nigeria allows agricultural activities and is settled by speakers of Gulmancema (Gourmanchéma), Zarma, Hausa, and Kanuri, whereas a much larger northern zone hosts mostly nomadic peoples who speak Arabic, Fulfulde, Tamajaq, and Tubu (Tedaga), and a few oasis dwellers who speak Tasawaq or Kanuri. There are only few Buduma speakers left in the country due to the drying up of Lake Chad. With the exception of the speakers of Tasawaq, all languages are of cross-border nature, i.e., they are also indigenous to neighboring countries, with even larger numbers therein.

Niger's population is predominantly Muslim (estimated 80–95%); traditional religions are adhered to by about 5% of the people and Christians comprise less than 0.5% (other sources have indicated up to 20% non-Muslims). About 85% of the population lives in rural areas; only 15% of these rural lands are suitable for agriculture.

Since obtaining independence from France in 1960, Niger has used French as the 'official language'; French is actively spoken by only about 10% of the population, however, and these people tend to be employed in the public sector and to have a background in formal educational, living in the capital Niamey and in administrative headquarters. With notable exceptions in the educational system and the media, French is the only language used for official purposes, i.e., in the domains of legislature, public administration, and jurisdiction, and in the formal economic sector. Occasionally and only for oral communication, French is supplemented by the use of Hausa and/or Zarma. In public life, the African languages are practically invisible. There is little demand outside expert circles for the empowerment of these languages, which generally suffer from negative attitudes on the part of many of their speakers. However, following democratization in the early 1990s, politicians seeking (re-)election have shifted from their 'French-only' mannerism to occasional usage of national languages. French remains associated with power and prestige, upward social mobility, successful professional careers, employment in the public sector, etc. in a very elitist way. The educational system is based almost exclusively on the 'imported' language, which most children do not speak on entering school, resulting in drastic school failure (frequent class repetitions or total abandonment of education). This conspires toward restricting access to higher education, and an inadequate command of the official language ultimately contributes to social exclusion and a potential for social violence.

The *Ethnologue* (2004) lists 20 spoken languages for Niger. Ten languages have constitutionally recognized legal status as 'national languages', with the following official spellings: *Arabe*, *Buduma*, *Fulfulde*, *Gulmancema*, *Hausa*, *Kanuri*, *Soŋay-Zarma*, *Təmajaq*, *Tassawaq*, and *Tubu*. This means that members of three of the four African language phyla of the Greenbergian language classification are represented: Afroasiatic (Arabic (Semitic), Buduma and Hausa (Chadic), and Tamajaq (Berber)); Nilosaharan (Kanuri and Tubu (Saharan) and Zarma (Songai));

Niger-Congo Languages

J Bendor-Samuel, Summer Institute of Linguistics
High Wycombe, UK

© 2006 Elsevier Ltd. All rights reserved.

It is widely accepted that the languages of Africa, apart from the creoles, pidgins, and 'official' languages inherited from the colonial era, belong to four major families: Niger-Congo, Nilo-Saharan, Afro-Asiatic, and Khoisan. Niger-Congo is the largest, both in terms of the number of languages and in geographical spread. It extends from Dakar east to Mombasa and south to Cape Town. Of the 2000 languages spoken in Africa, some 1400 belong to Niger-Congo. Recent estimates put the number speaking a Niger-Congo language at around 400 million people.

Early Classification

In the 19th century, scholars began to make groupings of African languages. Koelle (1854) published word lists in some 200 languages, grouped so as to reflect the relationships among the languages. Many of his groupings correspond closely to the accepted classification today.

Bleek (1856) recognized that languages in western and southern Africa were related and wrote of "that great family which, with the exception of the Hottentot dialects, includes the whole of southern Africa and most of the tongues of western Africa."

Subsequently, scholars tended to lose sight of the essential unity of these languages and to focus on the Bantu languages of southern Africa. The large number of languages elsewhere that had similar features were regarded as being 'mixed' in origin, and their similarities were explained as being the result of migrations and language contact, rather than as deriving from a common genetic origin with Bantu.

Significant development came with the work of Westermann (1927). He set up 'Western Sudanic' as distinct from 'Eastern Sudanic' (since classified as Nilo-Saharan). Westermann divided Western Sudanic into six subfamilies: Kwa, Benue-Congo, Togo Remnant, Gur, West Atlantic, and Mandingo (Maninka). He also compared a large number of proto-Western Sudanic roots with the corresponding proto-Bantu forms. Though Westermann did not go on to draw the conclusion that pointed to a common genetic origin, Joseph Greenberg did. He showed that Westermann's Western Sudanic and Bantu formed a single genetic family, which he called 'Niger-Congo.' Subsequently, Greenberg (1963) brought in Kordofanian as coordinate with Niger-Congo.

Greenberg retained the subfamilies that Westermann had already established – Kwa, Benue-Congo, Gur, West Atlantic, and Mande (Mandingo) – but included Togo Remnant within Kwa and added a new subfamily, which he termed 'Adamawa-Eastern.' His most revolutionary innovation was to include Bantu as a subgroup of a subgroup within Benue-Congo and not as a subfamily coordinate with the other main branches of Niger-Congo.

Accepted Classification

Although Greenberg's work has set the classificatory framework within which most scholars have worked since (Figure 1), there were, as he readily

Figure 1 Greenberg's classification.

admitted, still many unresolved classificatory questions. Subsequent research has clarified some of these issues, and Greenberg's classification was revised by a group of scholars (Bendor-Samuel, 1989) (Figure 2). The languages that are spoken today are classified into nine major language subfamilies: Mande, Kordofanian, Atlantic, Ijoid, Kru, Gur, Adamawa-Ubangi, Kwa, and Benue-Congo. Scholars are not agreed on the classification of Dogon; hence, it is listed separately, though it does not constitute a subfamily.

These nine major language subfamilies relate to each other in different ways, some being related more closely than others. The relationships reflect the fact that the nine major subfamilies did not derive directly from a common ancestor. There were intermediate steps that have been tentatively reconstructed on the chart.

Since the publication of *The Niger-Congo languages* (Bendor-Samuel, 1989), further consideration has been given particularly to three issues:

1. Although it is generally accepted that the five subfamilies of Kru, Kwa, Benue-Congo, Gur, and Adamawa-Ubangi are related more closely to each other than to Mande, Kordofanian, Atlantic, and Ijoid, there is no agreement on the sequence in which Mande, Kordofanian, Atlantic, and Ijoid split from the main stock. Some have suggested Kordofanian was the first to split off; others have proposed Mande.
2. As regards the Volta-Congo group, one view gaining acceptance is that the five subfamilies fall into two groups: Gur, Adamawa-Ubangi, and Kru in North Volta-Congo and Kwa and Benue-Congo in South Volta-Congo. It has been suggested that Gur and Adamawa-Ubangi originated as a dialect continuum. Kwa and Benue-Congo could be treated in the same way. Although geographically separated from Gur, Kru is related more closely to Gur than to any of the other languages in Volta-Congo and so is placed in the Northern group. The attraction of this analysis is that it provides for a northern and southern spreading of languages in the Volta-Congo group, with Gur and Adamawa-Ubangi spreading across the Savannah lands to the north of this area, in contrast to Kwa and Benue-Congo spreading to the south (see Williamson and Blench, 2000).
3. Discussion has continued about where to draw the boundary between Kwa and Benue-Congo. Some have followed Greenberg in regarding the western groups of languages in Benue-Congo as an eastern group within Kwa. Others draw the boundary farther to the west, with these languages grouped within Benue-Congo, as is the case in this article (Williamson and Blench, 2000).

One thing is clear from the continuing discussion: the classification of Niger-Congo is far from final. Many questions are still being asked about the internal structures of the present subfamilies, their relationship to each other within Niger-Congo, and the relationship of Niger-Congo itself to Nilo-Saharan (Williamson and Blench, 2000).

The Niger-Congo Subfamilies

Mande

Mande languages are spoken by over 10 million people over a wide area, including large parts of Guinea, Mali, Sierra Leone, Liberia, and northwest Ivory Coast. Substantial numbers are also found in Burkina Faso, Senegal, Gambia, and Guinea-Bissau, with much smaller pockets in southern Mauritania; northern parts of Ghana, Togo, Benin, and Nigeria; and in southwest Niger.

The internal relationships of the languages within the Mande subfamily are loose. Lexicostatistical studies give only 17% cognates between the Western and Eastern groups.

The much larger Western group, with 27 languages, divides into a Southwestern group of 4 languages and a Northwestern group of 23 languages. Within the Northwestern group, the core group comprises 10 languages, all scoring from 80–90% lexicostatistically, with three of those languages – Bambara (Bamanakan), Maninka, and Jula – being major languages with over 1 million speakers each.

The 13 languages within the Eastern group relate to each other at levels of 30–35% lexicostatistically.

Kordofanian

Kordofanian languages are isolated from the rest of the languages of Niger-Congo, being spoken in the Nuba mountains of central Sudan by 250 000–500 000 people.

Figure 2 Revised classification.

Kordofanian is divided into four main groups: Heiban, Talodi, Rashad, and Katla. Greenberg included a fifth group, Kadugli, but it is so divergent from the others that there is serious doubt whether it belongs to Kordofanian but rather to Nilo-Saharan (see Schadeberg, 1981).

Atlantic

Atlantic languages are spoken by about 20 million people. One language, Fula, accounts for 12–15 million of those people and is the most widely scattered language group in Africa, all the way from Senegal to the Sudan. Except for Fula, the Atlantic languages are located primarily along the Atlantic coast from the Senegal River to Liberia.

All of the Atlantic languages fall into one of two groups, northern and southern, except for the languages spoken on the Bijago Islands, which constitute a small third group with 20 000 speakers.Within the northern group, which includes Fula, Wolof, Serer, Jula (Jola), Manjaku-Papel, and Balanta (Balant-Ganja), lexicostatistical percentages range between 24–37.

The languages in the southern group are generally not related closely to each other. Three subgroups are recognized; Mel is the largest, comprising 13 languages, of which Temne (1 million speakers) and Bullom-Kissi (650 000) have the most speakers.

Ijoid

Ijoid is very different from the other subfamilies of Niger-Congo. It comprises the language cluster Ijo and a single language, Defaka. Ijo is not a single language, but a cluster of rather closely related languages/dialects with a total of over one million speakers. The whole subfamily is confined geographically to the Niger Delta. Ijoid does not belong either to Kwa or to Benue-Congo and seems to be outside the Volta-Congo grouping. Hence, it is treated as a branch of Atlantic-Congo.

Kru

Kru languages have been included by some scholars, including Greenberg, within Kwa, but later studies suggest that Kru is closer to Gur. Some have gone further and included Kru in a North Volta-Congo group together with Gur and Adamawa-Ubangi.

The 26 Kru languages are spoken by approximately 2 million people, mostly in the forest regions of southwest Ivory Coast and southern Liberia.

An Eastern and a Western group are recognized. The Western group is the larger and more heterogeneous and can be divided into four subgroups, each of which has one principal language complex: Grebo, Guere (Guere-Krahn), Bassa, and Klao. The Eastern group is more homogeneous and comprises two major subgroups, the Bete and the Dida language complexes, both in Ivory Coast.

Gur

The 85 Gur languages are found in the savannah lands north of the forest belt extending from southeast Mali across northern Ivory Coast, Burkina Faso, Ghana, Togo, and Benin into northwest Nigeria. The number of speakers of these languages is around 12–15 million.

Most Gur languages belong to Central Gur, which is a comparatively closely related group of languages. Within Central Gur, there are two major subgroupings, that of the Oti-Volta (some 25 languages) and Grusi (20 languages). Additionally, there are some 15 languages outside these two main subgroups. The

Figure 3 Benue-Congo subfamily.

languages within Oti-Volta show appreciably closer relationships to each other than do the languages within Grusi.

To the west of Central Gur lies the Senufo subgroup, comprising some 20 languages, grouped into 7 subgroups. Its relationship to Central Gur is not close, but there is no evidence to group Senufo with any other subfamily.

Dogon

Dogon is spoken in Mali, east of Mopti. Previously, scholars had included it within Gur, but there is general agreement that the grounds for this classification are inadequate. However, there is no evidence to group it with any of the other subfamilies within Volta-Congo.

Adamawa-Ubangi

Adamawa-Ubangi languages are spoken by approximately 8–9 million people from eastern Nigeria across northern Cameroon, southern Chad, the Central African Republic, and northern Zaire into southwestern Sudan.

Some lexicostatistical studies suggest that the Adamawa-Ubangi languages are closer to some of the Gur languages than they are to any of the languages in the other subfamilies within Volta-Congo. A preliminary hypothesis groups Gur and Adamawa-Ubangi in a North Volta-Congo grouping.

The languages within the Adamawa group are found mostly in Nigeria and Cameroon and are rather loosely related. The 70 plus languages/dialects are divided into 16 groups.

The Ubangi group has a larger number of speakers. The languages in it are related more closely to each other and include a number of widely spoken languages, such as Banda, Ngbandi, Ngbaka (Ngbaka-Mba), Gbaya, and Zande. The most probable classification suggests a core group comprising the three subgroups Banda, Ngbandi, and Ngbaka, with two peripheral groups Gbaya and Zande.

Kwa

The 45 Kwa languages stretch across southern Ivory Coast, Ghana, Togo, Benin, and into the southwest corner of Nigeria, with a total of at least 20 million speakers.

This subfamily divides broadly into two main groups. The larger group, Nyo, comprises some 24 language clusters/languages/dialects covering most of southern Ghana and southeastern Côte d'Ivoire. Within Nyo, Potou-Tano is the largest subgroup with some 17 languages/dialects, including the major languages Akan (Twi and Fanti), Baule (Baoule), and the Guang cluster.

The smaller group, sometimes termed 'left bank' because its speakers live east of the Volta river, comprises seven language clusters/languages, of which the Gbe cluster (better known by the name of its largest member, Ewe) is the largest.

Benue-Congo

Benue-Congo is the largest of the subfamilies within Niger-Congo in terms of the number of languages, speakers, and geographical extent. It stretches from the Benin-Nigeria border across Nigeria eastward to Kenya and southward to the Cape. Thus, it covers over half the habitable terrain of the continent and a similar percentage of the population.

Benue-Congo is divided into 11 groups that can be arranged on an approximately west-to-east basis as in Figure 3.

Figure 4 Bantu's genetic relationships.

All these groups, with the exception of Bantoid, are found primarily in Nigeria. The principal languages of each group are as follows: Defoid: Yoruba and Igala; Edoid: Edo and Urhobo; Nupoid: Nupe, Ibira (Ebira), and Gwari (Gbagyi); Idomoid: Idoma and Igede; Igboid: Igbo; Cross River: Efik, Ibibio, and Ogoni; Kainji: Kambari; Platoid: Berom, Tarok, and Jukun.

The 11th group, Bantoid, is the largest group in Niger-Congo, comprising several hundred languages, covering most of the area southeast of Nigeria and Chad.

Bantoid is divided into a small northern group of languages spoken in eastern Nigeria and western Cameroon, and the very much larger southern group, which includes all the Bantu languages. Bantu's genetic relationships are illustrated in Figure 4 (*see* **Bantu Languages**).

Nigeria is the largest nation in sub-Saharan Africa, with approximately 25% of the population of the subcontinent. At the time of writing, reliable census figures are not available; estimates of Nigeria's population range from 80 million to 120 million. Linguistically speaking, it is one of the most complex countries in the world, with approximately 440 languages (Crozier and Blench, 1993), comprising over 20% of Africa's 2000 plus languages. The most widely accepted classification of African languages (Greenberg, 1963, and subsequent modifications) postulates four major phyla for the continent: Niger–Congo, Afro–Asiatic, Nilo–Saharan, and Khoisan; all but the last of these are well represented in Nigeria. Nigeria's linguistic complexity is manifested first in the mere existence of such a large number of languages within one nation's borders, and second in the attendant situation of multilingualism, and its implications for development and education.

Niger: Language Situation

H E Wolff, University of Leipzig, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Republic of Niger covers a landlocked territory of 1.27 million km^2 in the semiarid and arid zones of the southern Sahara, bordering on Nigeria, Burkina Faso, Mali, Algeria, Libya, and Chad. The population in 2001 was approximately 11 million. A narrow southern zone in the valley of the river Niger and along the border to Nigeria allows agricultural activities and is settled by speakers of Gulmancema (Gourmanchéma), Zarma, Hausa, and Kanuri, whereas a much larger northern zone hosts mostly nomadic peoples who speak Arabic, Fulfulde, Tamajaq, and Tubu (Tedaga), and a few oasis dwellers who speak Tasawaq or Kanuri. There are only few Buduma speakers left in the country due to the drying up of Lake Chad. With the exception of the speakers of Tasawaq, all languages are of cross-border nature, i.e., they are also indigenous to neighboring countries, with even larger numbers therein.

Niger's population is predominantly Muslim (estimated 80–95%); traditional religions are adhered to by about 5% of the people and Christians comprise less than 0.5% (other sources have indicated up to 20% non-Muslims). About 85% of the population lives in rural areas; only 15% of these rural lands are suitable for agriculture.

Since obtaining independence from France in 1960, Niger has used French as the 'official language'; French is actively spoken by only about 10% of the population, however, and these people tend to be employed in the public sector and to have a background in formal educational, living in the capital Niamey and in administrative headquarters. With notable exceptions in the educational system and the media, French is the only language used for official purposes, i.e., in the domains of legislature, public administration, and jurisdiction, and in the formal economic sector. Occasionally and only for oral communication, French is supplemented by the use of Hausa and/or Zarma. In public life, the African languages are practically invisible. There is little demand outside expert circles for the empowerment of these languages, which generally suffer from negative attitudes on the part of many of their speakers. However, following democratization in the early 1990s, politicians seeking (re-)election have shifted from their 'French-only' mannerism to occasional usage of national languages. French remains associated with power and prestige, upward social mobility, successful professional careers, employment in the public sector, etc. in a very elitist way. The educational system is based almost exclusively on the 'imported' language, which most children do not speak on entering school, resulting in drastic school failure (frequent class repetitions or total abandonment of education). This conspires toward restricting access to higher education, and an inadequate command of the official language ultimately contributes to social exclusion and a potential for social violence.

The *Ethnologue* (2004) lists 20 spoken languages for Niger. Ten languages have constitutionally recognized legal status as 'national languages', with the following official spellings: *Arabe*, *Buduma*, *Fulfulde*, *Gulmancema*, *Hausa*, *Kanuri*, *Soŋay-Zarma*, *Təmajaq*, *Tassawaq*, and *Tubu*. This means that members of three of the four African language phyla of the Greenbergian language classification are represented: Afroasiatic (Arabic (Semitic), Buduma and Hausa (Chadic), and Tamajaq (Berber)); Nilosaharan (Kanuri and Tubu (Saharan) and Zarma (Songai));

and Niger-Congo (Fulfulde (Atlantic) and Gulmancema (Voltaic)), plus Tasawaq (possibly a creole of mixed Songai-Berber origin; research on its origins is still in progress).

The 10 indigenous national languages in the following list are of very distinct sociolinguistic nature. Half of them (Arabic, Buduma, Gulmancema, Tasawaq, and Tubu) have pronounced minority status, and they are each spoken by only a few thousand people. In terms of numbers of speakers (and with figures differing according to source), the midfield is covered by Kanuri (4–7%) in the southeast, Tamajaq (8–11%) in the vast northwest (but more recently settling further south), and Fulfulde (9–14%), with speakers scattered across most parts of the country. Hausa and, to a much lesser extent, Zarma, stand out as Niger's most prominent national languages and indigenous lingua francas in terms of being both the first and the second languages among the greatest number of users.

1. Arabic. Spoken by about 0.3% of the population; the nomenclature refers to the mother tongue of small local groups, not to classical or 'lingua franca' Arabic. The *Ethnologue* lists four varieties of spoken Arabic in Niger: Algerian Saharan Arabic (10 000 speakers around Agadez and in the Azaouagh region), Hassaniya Arabic (with most of its 10 000 speakers in Mauritania), Libyan Arabic (5000 speakers in eastern Niger north of N'Guigmi), and Shuwa Arabic (5000 in eastern Niger).
2. Buduma (Yedina). Traditionally spoken by people who live on the shores and islands of Lake Chad; their language is – surprisingly, and possibly incorrectly – no longer listed for Niger in the 2004 *Ethnologue*, quite likely due to heavy migration of Buduma speakers into Chad, following the receding waters of Lake Chad eastward.
3. Fulfulde. Listed as being of two main varieties in the 2004 *Ethnologue*: a central-eastern variety, spoken from around Dogondoutchi and eastward to the Chad border (450 000 speakers), including the nomadic Woɗaaɓe (dialect, 'people of the taboo'), plus a western variety (400 000 speakers), spoken between the Burkina Faso border and Dogondoutchi (dialects: Dallol and Bitinkoore).
4. Gulmancema (*Ethnologue*: Gourmanchéma). Spoken by about 0.3% of the population along the southwestern border with Burkina Faso.
5. Hausa. Mother tongue of an estimated 5 million speakers (55% of the population) and second language of about 80% of the speakers in Niger. It is widely spoken in major towns and in administrative posts across the country. Hausa dialectology is little advanced; the following dialects appear to be distinct varieties found in Niger in association with certain settlements or areas (given in parentheses): Kurfey (Filingué), Ader (Tahoua), Arewa (Dogondoutchi), Damagaram (Zinder), Dawra, Gaya, Gobir (Maradi), Katsina (Maradi), and Tibiri.
6. Kanuri. Listed in the 2004 *Ethnologue* as being of three varieties: Central Kanuri (80 000 speakers), in eastern Niger along the Nigerian border and including the oases of Fachi and Bilma; Manga Kanuri (280 000 speakers); and Tumari Kanuri (40 000 speakers), better known as Kanembu, including dialects such as Sugurti and Kubari, in far eastern N'Guigmi and neighboring villages.
7. Tasawaq (*Tassawaq*). Spoken by about 8,000 people in the oasis of In-Gall and in the neighboring salt-mines of Teguidda-n-Tessoumt. Closely related Tagdal (Tihishit) is spoken by the Igdalen and Iberogan (dialect: Tabarog), with about 25 000 speakers between Agadez and Tahoua. Together with Tasawaq (or Ingelsi) and others, these languages are referred to in the specialized literature as Northern Songai, also including the extinct language of the Agadez area, Emghedeshie, mentioned by the German explorer Heinrich Barth in the 1850s.
8. Tamajaq (*Təmajaq*). One of several designations for the language spoken by the Tuareg (plural; cf. sg. masc. Targi, sg. fem. Targia). The 2004 *Ethnologue* lists three varieties: Tamahaq (or Tahaggart, with 20 000 speakers around the Hoggar Mountains and Tamanrasset), Tamajaq (or Tawallammat, with 450 000 speakers), and Tamajeq (or Tayart, with 250 000 speakers around the Aïr Mountains and Agadez).
9. Tubu. Spoken by about 0.4% of the population, the name is a cover term for speakers of two related languages, i.e., Teda (*Ethnologue*: Tedaga; 10 000 speakers) and Daza (*Ethnologue*: Dazaga; 30 000 speakers). These varieties are spoken in the extreme east and northeast, in Termit, N'Gourti, Bilma, and Djado.
10. Zarma (*Soŋay-Zarma*). Mother tongue of an estimated 2.2 million speakers (22% of the population) and the second language of 30% of the speakers; alternate names include Dyerma, Djerma, Zerma, and Zabarma, among others. Zarma is part of a language continuum along the river Niger from Mali (Gao, language: Songai) into Niger (Zarma; dialect: Kaado) and then turning south into Benin (language: Dendi).

Bi- and multilingualism are widespread in Niger, largely involving Hausa and/or Zarma as the principal lingua francas, but also French to some extent.

Hausa and/or Zarma can be understood by up to 90% of the total population across the whole country. There are also large pockets of monolingual communities, especially in the rural areas. Any revision of the language policy in terms of 'official language(s)' would have to be based on a trilingual model of Hausa, Zarma, and French.

Niger's multilingualism is paralleled to a lesser extent by multiscriptism: orthographies using modified versions of the Roman alphabet are available for all national languages in Niger. In addition, the Tuareg have a long tradition of writing in the *tifinagh* script, which has its origins in the Phoenician script. Arabic writing known as *àjàmí* is also in use for non-Arabic languages.

Since achieving independence, Niger has developed a remarkable record for efforts regarding adult literacy (both in French and in the national languages) and bilingual formal education on primary level, despite a persistent high rate of illiteracy (over 80%), which is still higher among women (over 90%). School attendance has generally been low in the past (below 30%); recent figures from official sources draw a much brighter picture of school attendance (about 50% in 2004), including a considerable increase in female pupils. Formal education on all levels is dominated by French language use, but bilingual French-Arabic schools (*medersas*) and the Arabic-medium Islamic University of Say are allowed, and there is continuing experimentation with bilingual (French plus a national language) education. In 1998, an education bill establishing French and the national languages as the media of instruction was passed, prescribing mother-tongue primary education for 6 years. The bill awaits implementation. By 1998, 42 bilingual experimental schools, having begun in 1973, were in existence; 22 of these schools officially use Hausa, 6 use Zarma, 5 use Fulfulde, 5 use Tamajaq, and 4 use Kanuri as the medium of instruction, in addition to French. Several governmental and nongovernmental institutions provide materials and training for formal education based on national language competence. In the informal education sector, qur'anic schools play a continuing role. These schools, however, have no impact on oral and writing skills in the Arabic language, other than aiming at oral and, at the advanced stage, written recitation skills of the Qur'an.

In the electronic and print media, a similar dominance of French as the only official language is notable, particularly in the print media, such as in all of the major newspapers. However, indigenous languages have some record of having been used in the print media since 1965, including nationwide distribution of *Ganga* ('drum') in both Hausa and Zarma, printing of special pages of the weekly *Sahel Hebdo*, and creation of a rural press (*journaux ruraux*) in the 1970s. In the early 1990s, the weekly *Kakaki* ('(Emir's) trumpet') was established for indigenous language usage. Given a long-standing high illiteracy rate, radio and later television (the Office de Radiodiffusion-Télévision du Niger, or the ORTN) became of prime importance. About 65% of the programs are by now transmitted in indigenous languages, i.e., in all the national languages (possibly with the exception of Tasawaq), and this is accompanied by a steady decentralization policy. Private radio stations are now being established in urban areas, broadcasting in Hausa, Zarma, and French, which are the major languages found among urban listeners. They also broadcast popular Hausa language programs taken from *Voice of America* and *Deutsche Welle*. The United Nations Development Program (UNDP) has become active in establishing noncommercial rural radio stations that broadcast in the local indigenous languages, including programs even in the otherwise largely neglected languages Buduma (in N'Guigmi) and Tasawaq (in In-Gall). Daily television programs on *Télé-Sahel* (ORTN) are broadcast in one of seven national languages. The first private television station (*TV Ténéré*) broadcasts programs in Hausa, Zarma, and French.

Niger-Congo Languages

J Bendor-Samuel, Summer Institute of Linguistics
High Wycombe, UK

© 2006 Elsevier Ltd. All rights reserved.

It is widely accepted that the languages of Africa, apart from the creoles, pidgins, and 'official' languages inherited from the colonial era, belong to four major families: Niger-Congo, Nilo-Saharan, Afro-Asiatic, and Khoisan. Niger-Congo is the largest, both in terms of the number of languages and in geographical spread. It extends from Dakar east to Mombasa and south to Cape Town. Of the 2000 languages spoken in Africa, some 1400 belong to Niger-Congo. Recent estimates put the number speaking a Niger-Congo language at around 400 million people.

Early Classification

In the 19th century, scholars began to make groupings of African languages. Koelle (1854) published word lists in some 200 languages, grouped so as to reflect the relationships among the languages. Many of his groupings correspond closely to the accepted classification today.

Bleek (1856) recognized that languages in western and southern Africa were related and wrote of "that great family which, with the exception of the Hottentot dialects, includes the whole of southern Africa and most of the tongues of western Africa."

Subsequently, scholars tended to lose sight of the essential unity of these languages and to focus on the Bantu languages of southern Africa. The large number of languages elsewhere that had similar features were regarded as being 'mixed' in origin, and their similarities were explained as being the result of migrations and language contact, rather than as deriving from a common genetic origin with Bantu.

Significant development came with the work of Westermann (1927). He set up 'Western Sudanic' as distinct from 'Eastern Sudanic' (since classified as Nilo-Saharan). Westermann divided Western Sudanic into six subfamilies: Kwa, Benue-Congo, Togo Remnant, Gur, West Atlantic, and Mandingo (Maninka). He also compared a large number of proto-Western Sudanic roots with the corresponding proto-Bantu forms. Though Westermann did not go on to draw the conclusion that pointed to a common genetic origin, Joseph Greenberg did. He showed that Westermann's Western Sudanic and Bantu formed a single genetic family, which he called 'Niger-Congo.' Subsequently, Greenberg (1963) brought in Kordofanian as coordinate with Niger-Congo.

Greenberg retained the subfamilies that Westermann had already established – Kwa, Benue-Congo, Gur, West Atlantic, and Mande (Mandingo) – but included Togo Remnant within Kwa and added a new subfamily, which he termed 'Adamawa-Eastern.' His most revolutionary innovation was to include Bantu as a subgroup of a subgroup within Benue-Congo and not as a subfamily coordinate with the other main branches of Niger-Congo.

Accepted Classification

Although Greenberg's work has set the classificatory framework within which most scholars have worked since (**Figure 1**), there were, as he readily

Figure 4 Bantu's genetic relationships.

All these groups, with the exception of Bantoid, are found primarily in Nigeria. The principal languages of each group are as follows: Defoid: Yoruba and Igala; Edoid: Edo and Urhobo; Nupoid: Nupe, Ibira (Ebira), and Gwari (Gbagyi); Idomoid: Idoma and Igede; Igboid: Igbo; Cross River: Efik, Ibibio, and Ogoni; Kainji: Kambari; Platoid: Berom, Tarok, and Jukun.

The 11th group, Bantoid, is the largest group in Niger-Congo, comprising several hundred languages, covering most of the area southeast of Nigeria and Chad.

Bantoid is divided into a small northern group of languages spoken in eastern Nigeria and western Cameroon, and the very much larger southern group, which includes all the Bantu languages. Bantu's genetic relationships are illustrated in **Figure 4** (*see* **Bantu Languages**).

Nigeria: Language Situation

B A Connell, York University, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2803–2804, © 1994, Elsevier Ltd.

Nigeria is the largest nation in sub-Saharan Africa, with approximately 25% of the population of the subcontinent. At the time of writing, reliable census figures are not available; estimates of Nigeria's population range from 80 million to 120 million. Linguistically speaking, it is one of the most complex countries in the world, with approximately 440 languages (Crozier and Blench, 1993), comprising over 20% of Africa's 2000 plus languages. The most widely accepted classification of African languages (Greenberg, 1963, and subsequent modifications) postulates four major phyla for the continent: Niger–Congo, Afro–Asiatic, Nilo–Saharan, and Khoisan; all but the last of these are well represented in Nigeria. Nigeria's linguistic complexity is manifested first in the mere existence of such a large number of languages within one nation's borders, and second in the attendant situation of multilingualism, and its implications for development and education.

Despite the diversity, three languages (putting aside English for the time being) dominate: Hausa in the north, spoken as a first language by about 20% of the population (with perhaps an equal number of second language users); Yoruba in the west, by about 25%; and Igbo in the east, spoken by perhaps 20% of Nigerians. The remaining 35% are speakers of the so-called 'minority' languages, many of which are spoken by only a few thousand, or less. Of these, Ibibio in the southeast and Kanuri in the northeast are the largest, each being spoken by about 3% of Nigerians. English, the colonial language brought to Nigeria, is also relatively widely spoken, at least by the educated. Estimates vary, however, as to what percentage of the population use English with any degree of fluency, with claims from 10 to 30%. Determining the extent of English use is complicated by consideration of Nigerian Pidgin, which, at the more elaborated end of its spectrum, merges with English. Nigerian Pidgin is spoken by perhaps as much as 30% of the population, mostly in the south, but is also increasingly used in the northern urban areas.

With regard to government attitude toward language, there is, at the time of writing, no specifically formulated language policy. The importance of choice of language with regard to education, however, has been recognized since the early days of the British colonial administration, which sought to implement the recommendations of the Phelps-Stokes Commission (1922) concerning the use of indigenous languages in schooling. Two documents that can be regarded as policy statements do exist, however, one being the Constitution of 1979 (revised 1989) and the other, the National Policy on Education (1977, revised 1981). The National Policy on Education (NPE) essentially echoes the Phelps-Stokes Report in presenting a three-stage program with regard to language use in education: first, that preprimary instruction should be in the mother tongue or language of the immediate community; second, that at the primary level, instruction should initially be in the mother tongue or language of the immediate community, and later in English; and third, that in secondary school one of the three major languages, as well as the language of the community, should be taught. Subsequently, another Nigerian language is also to be included as a core subject. The need for a mass literacy campaign is also recognized in the NPE.

Implementation of the various aspects of this policy is to be accomplished through the development of indigenous languages, by the creation of orthographies and dictionaries, and the writing of primers and other textbooks. Various agencies have been established to help achieve these goals, ranging from the National Language Centre (now under the Nigerian Educational Research Development Council) and Mass Literacy Boards, to University Departments of Linguistics. The Policy stipulates that this program should be implemented when (economically) feasible, and as a result in most areas of the country full implementation has yet to be achieved. At the time of writing, only 20 languages have officially sanctioned (standardized) orthographies, although over 100 others also have been given writing systems. The outlook for increased future development is not encouraging, as all questions dealing with language have been struck from the 1991 census. On the other hand, State governments, which are responsible for broadcast media, appear to be more active in encouraging use of local languages, although this attitude varies from state to state. Bornu State, for example, encourages use of 17 local languages, while in many southern states, news and feature programs are broadcast in Nigerian Pidgin.

The National Policy on Education and the Federal Constitution also recognize the role of language in fostering national unity. Regarding 'official' or 'national' designations of languages, the 1979 Constitution recognizes the three major languages, Hausa, Yoruba, and Igbo, and stipulates that any of these three may be used, along with English, in the National and State Assemblies. The status and role of English is controversial. Although many Nigerians feel it is now time for an indigenous language to take on the role of lingua franca, there is no ethnically neutral language able to assume this mantle. English, therefore, continues to function as the major language of communication among the educated of different ethnic groups. Nigerian Pidgin, despite its widespread use, has no official recognition and for the most part is regarded by the ruling and educated elite as a bastardized form of English. Its increasing popularity in the towns and cities, and especially on university campuses, however, suggests that in the not too distant future its status may change.

A high degree of multilingualism exists in the country. Few, if any, detailed studies have been conducted, but the following remarks can be assumed to be accurate. Among speakers of minority languages, greater multilingualism exists. This usually takes the form of speaking (a) the mother tongue and having at least passive knowledge of one or more neighboring and closely related languages, (b) in the south, and particularly urban areas, Nigerian Pidgin, or in the north, Hausa (i.e., for non-Hausas), and (c) for the educated, English. Most Nigerians, then, are at

least bilingual, and probably multilingual; for the most part, monolingualism exists only among the uneducated in the heartlands of the three largest languages. As regards lingua franca, English, Pidgin, and Hausa all serve, with the choice depending on geographical and social considerations. Together with studies dealing with sociolinguistics and multilingualism, descriptive and comparative/historical work constitute major areas for future linguistic research in Nigeria.

T. M. Nikolaeva was born in 1933 in Leningrad, into a family of scholars renowned in the field of theoretical medicine. In 1956, she graduated from the department of Russian language and literature, Moscow State University; she was influenced mostly by the lectures of V. V. Vinogradov, Vjach. Vs. Ivanov, and V. A. Zvegintsev. Besides her major-related courses, she attended lectures on Sanskrit, Indo–European Linguistics, Hittite, and Latin.

From 1958 till 1962, she was a graduate student of A. A. Reformatski at the Institute of Linguistics. At approximately the same time, from 1957 till 1960, she worked as a member of the Group of Automatic Machine Translation (Institute of Fine Mechanics and Computer Engineering, Russian Academy of Sciences).

When, in 1960, a section of structural linguistics was created under the auspices of the Section of Language and Literature RAS (Russian Academy of Sciences), Nikolaeva was appointed the learned secretary of the Department of Typology, first holding the position of a junior researcher, later becoming a senior researcher, and then a principal researcher. Since 1990, Nikolaeva has been head of the department of typological and comparative linguistics at the Institute for Slavic Studies RAS.

Nikolaeva is an outstanding specialist in theoretical linguistics, text theory, linguistic typology, Slavic and specifically Russian linguistics, phrasal intonations, and word prosody. All of these topics are covered in her numerous publications (numbering over 420, including 10 books).

Part of Nikolaeva's research (carried out according to the principles of the Moscow Semiotic School) is focused on the properties of poetic texts, such as Silver Age verses of contemporary poetry. In 2001, she arranged a conference on 'Proper name: semantic aura and context,' inspiring many scholars to begin investigating the problem of linguistic detachment of a proper name. Nikolaeva edited and prepared for publication important collections of scholarly papers, such as *Text linguistics* (1978) and *From the oeuvre of the Moscow Semiotic Circle* (1997).

Nikolaeva was the first scholar to produce a whole and thorough description of intonational systems in Slavic languages; she worked out principles for the typologically oriented study of phrasal intonation, having also introduced such currently universally accepted terms as, for instance, 'prosodic scheme of a word,' being a correspondence of what is labeled a 'soundclass' in segmental phonetics.

Nikolaeva is the editor-in-chief of the journal *Voprosy Jazykoznanija* and a member of several international societies and committees. She has also been a corresponding member of the Russian Academy of Sciences since 2000.

least bilingual, and probably multilingual; for the most part, monolingualism exists only among the uneducated in the heartlands of the three largest languages. As regards lingua franca, English, Pidgin, and Hausa all serve, with the choice depending on geographical and social considerations. Together with studies dealing with sociolinguistics and multilingualism, descriptive and comparative/historical work constitute major areas for future linguistic research in Nigeria.

Nilo-Saharan Languages

G J Dimmendaal, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

One of Africa's major language phyla, Nilo-Saharan consists of at least 120 languages spoken in an area covering major areas in eastern and central Africa, with a westward extension as far as the Niger Valley in Mali, West Africa. The genetic unity of these languages was first proposed by Greenberg (1963) on the basis of recurring morphological features and lexical similarities. According to Greenberg, Nilo-Saharan constitutes one of the four phyla on the continent, next to Afroasiatic, Khoisan, and Niger-Congo.

Greenberg initiated his classificatory work on African languages in the late 1940s and early 1950s when he established, among others, a Macro-Sudanic family, consisting of Eastern Sudanic, Central Sudanic, Berta, and Kunama (cf. Greenberg, 1955, which contains a collection of articles published earlier in the *Southwestern Journal of Anthropology*). Macro-Sudanic was subsequently renamed Chari-Nile, after the two major rivers in the area. Based on a judicious evaluation of the available data, Greenberg (1963) pulled together several disparate groups formerly considered linguistic isolates and known primarily through the pioneering work of Tucker and Bryan (1956) into a new phylum called Nilo-Saharan, of which Chari-Nile formed the core, with Songai (Songhay), Saharan, Maban plus Mimi, For (or Fur), and Koman as additional primary branches (see **Table 1**).

There are at least 120 distinct Nilo-Saharan languages, the number of speakers for individual languages ranging from several millions (compare the sections on Dinka, Kanuri, Luo, and the Songai cluster) to languages with only a few speakers, e.g., Aka, Kelo, and Molo, which belong to the Jebel group within Eastern Sudanic. Although considerable progress has been made over the past few decades with the description and comparison of several Nilo-Saharan subgroups, a number of lower-level units, for example Daju or Koman, remain poorly known.

Several Nilo-Saharan languages are used only in oral communication; for others orthographies in Latin, Arabic, or Fidäl script have been developed. Old Nubian, which was written in a modified Coptic script, dates back to the 8th century of the Christian era. The role of Nilo-Saharan languages in education also varies considerably depending on the number of speakers, and also on the language policy in the countries where these languages are spoken. For major languages such as Kanuri or Luo, but also for other languages, in particular those spoken in Kenya and Uganda, there is a growing body of literature containing novels, poetry, and oral traditions. Apart from written texts and reference grammars, dictionaries have become available more recently for several Nilo-Saharan languages, for example, Keegan (1996)

One of Africa's major language phyla, Nilo-Saharan consists of at least 120 languages spoken in an area covering major areas in eastern and central Africa, with a westward extension as far as the Niger Valley in Mali, West Africa. The genetic unity of these languages was first proposed by Greenberg (1963) on the basis of recurring morphological features and lexical similarities. According to Greenberg, Nilo-Saharan constitutes one of the four phyla on the continent, next to Afroasiatic, Khoisan, and Niger-Congo.

Greenberg initiated his classificatory work on African languages in the late 1940s and early 1950s when he established, among others, a Macro-Sudanic family, consisting of Eastern Sudanic, Central Sudanic, Berta, and Kunama (cf. Greenberg, 1955, which contains a collection of articles published earlier in the *Southwestern Journal of Anthropology*). Macro-Sudanic was subsequently renamed Chari-Nile, after the two major rivers in the area. Based on a judicious evaluation of the available data, Greenberg (1963) pulled together several disparate groups formerly considered linguistic isolates and known primarily through the pioneering work of Tucker and Bryan (1956) into a new phylum called Nilo-Saharan, of which Chari-Nile formed the core, with Songai (Songhay), Saharan, Maban plus Mimi, For (or Fur), and Koman as additional primary branches (see Table 1).

There are at least 120 distinct Nilo-Saharan languages, the number of speakers for individual languages ranging from several millions (compare the sections on Dinka, Kanuri, Luo, and the Songai cluster) to languages with only a few speakers, e.g., Aka, Kelo, and Molo, which belong to the Jebel group within Eastern Sudanic. Although considerable progress has been made over the past few decades with the description and comparison of several Nilo-Saharan subgroups, a number of lower-level units, for example Daju or Koman, remain poorly known.

Several Nilo-Saharan languages are used only in oral communication; for others orthographies in Latin, Arabic, or Fidäl script have been developed. Old Nubian, which was written in a modified Coptic script, dates back to the 8th century of the Christian era. The role of Nilo-Saharan languages in education also varies considerably depending on the number of speakers, and also on the language policy in the countries where these languages are spoken. For major languages such as Kanuri or Luo, but also for other languages, in particular those spoken in Kenya and Uganda, there is a growing body of literature containing novels, poetry, and oral traditions. Apart from written texts and reference grammars, dictionaries have become available more recently for several Nilo-Saharan languages, for example, Keegan (1996)

Table 1 Nilo-Saharan subgroups

Greenberg, 1955		*Greenberg, 1963, 1971*	*Current nomenclature*
Songhai	isolate	Songhai	Songai
Central Saharan	isolate	Saharan	Saharan
Maban	isolate	Maban	Maban
Mimi	isolate	Mimi	Mimi
Fur	isolate	Fur	For
Nyangiyan	isolate		Kuliak (also: Rub)
Temainian	isolate		Temein, Keiga Jirru
Nubian			Nubian
Beir-Didinga			Surmic
Barea			Nara
Tabi			(West) Jebel
Nyimang	Eastern Sudanic	Eastern Sudanic	Nyimang, Dinik
Merarit			Taman
Dagu			Daju
Nilotic			Nilotic
Great Lakes			
Central Sudanic			Central Sudanic
Berta			Berta
Kunama			Kunama
Koman	isolate		Koman

on the Central Sudanic language Mbay, Creider and Creider (2001) on Nilotic Nandi, or Heine (1999) on the Kuliak (Rub) language Ik.

More Recent Comparative Work

To date, neither the limits of Nilo-Saharan nor the internal organization has been settled. This situation is due to heterogeneity within the phylum (with several genetically isolated languages) and the presumably considerable time depth involved, as well as the paucity of descriptive sources for a variety of languages. The genetic status of the Songai cluster on the great bend of the Niger River, mainly in Mali and Niger and extending into neighboring countries, remains debatable, for example. However, as a result of the pioneering descriptive work on several varieties of Songai by Heath (e.g. 1999a), future in-depth comparative work with respect to this cluster may be expected.

Some progress has been made over the past decades with the historical comparison of lower-level units such as Central Sudanic, Daju, Koman, Maban, Nilotic, Nubian, Saharan, and Surmic. More recently, it has been argued by Rilly (2003) that the extinct language of the Meroitic empire, preserved in written records which have only been partly deciphered, not only shows Eastern Sudanic affinity, as already proposed by Greenberg (1971), but that it was most closely related to Eastern Sudanic groups such as Nubian, Taman, Nara, and Nyimang (plus Dinik).

On the basis of an extensive comparison of lexical entries, presumed sound correspondences, and grammatical comparison, Ehret (2001) has regrouped various Nilo-Saharan units; according to this classification using shared phonological and grammatical innovations for subclassification, Central Sudanic and Koman, which are also typologically rather distinct from remaining Nilo-Saharan groups, constitute genetic outlayers.

Bender (1996, 2000) has also proposed lexical isoglosses and grammatical isomorphs for Nilo-Saharan. Moreover, the same author assumes that Songai, Saharan, and Kuliak constitute primary branches of Nilo-Saharan, whereas the remaining subgroups form a fourth branch. Unlike Ehret, Bender assumes that the Koman group is most closely related to the Eastern Sudanic group. Moreover, he assumes, as other scholars have done, that the Kadu languages in the Nuba Mountains are also part of Nilo-Saharan.

Controversy also remains over the inclusion or exclusion of languages like Biraile (Birale; also known as Ongota), whose speakers live along the Weyt'o River in Ethiopia, and the Shabo (or Mekeyir), another small ethnic group living in southwestern Ethiopia.

The Areal Dimension

Corresponding to the wide geographical spread of Nilo-Saharan languages, considerable typological diversity exists between them. A number of properties nevertheless are widespread and in fact are shared with neighboring Niger-Congo, and to a lesser extent Afroasiatic, languages. For example, ATR-vowel harmony, in its classical form involving a set of [−advanced tongue root] vowels (I, ɛ, a, ɔ, ʊ), and a set of [+advanced tongue root] vowels (i, e, ä, o, u), is attested in varieties of Songai, For, Kunama, Eastern Sudanic groups like Nubian, Temein, Nilotic, and Surmic as well as in Koman languages. The role of areal contact in this respect remains to be determined. Less common are systems with seven vowels (e.g., in the Nilotic language Datooga) or five vowels (e.g., in Nara). As shown by Andersen (1991), the contrast between breathy and creaky voice vowels in the Nilotic language Dinka goes back historically to an ATR contrast.

Another areal property of Nilo-Saharan shared with neighboring Niger-Congo and Afroasiatic languages is tone, with systems varying between classical

two-tone systems with downdrift and downstep and systems with up to four distinct level tones which may also form complex (contour) tones. A number of Nilo-Saharan languages spoken along the northern edge and bordering on Afroasiatic, such as the Songai language Koyra Chiini, appear to be nontonal (Heath, 1999b). There are relatively few tonal grammars of Nilo-Saharan languages. Also, the historical-comparative study of tonal systems is still in its initial stage, Boyeldieu (2000) on a group of Central Sudanic languages being one of the few modern studies in this respect.

Consonant systems range from fairly simple, e.g., thirteen consonants in Southern Nilotic Kalenjin, to a wide range of contrasts in Central Sudanic and Koman languages. Here too, areal contact appears to have played a role; the Kalenjin consonant system, for example, is similar to that of neighboring Bantu (Niger-Congo) languages. Central Sudanic languages like Ngiti have a contrast between voiced and voiceless implosive stops, according to Kutsch Lojenga (1994); moreover, words in Ngiti as well as in the closely related language Lendu may consist of syllabic consonants like s, z, or r only. Whereas voiced implosive stops are more common across Nilo-Saharan, such stops are found in combination with ejectives in Berta, Koman and Surmic; a similar contrast is found in neighboring Omotic (Afroasiatic) languages. The dental/alveolar contrast for stops appears to berestricted to Eastern Sudanic groups like Nilotic, Surmic, Temein, Central Sudanic Kreish, or the Koman language Kwanimpa. Labial velars stops are common in Central Sudanic as well as neighboring Nilotic languages. The role of areal contact with Niger-Congo languages again remains to be determined.

A prototypical feature of many Nilo-Saharan groups, which appears to be relatively rare elsewhere in the world (except in Cushitic and Semitic, i.e., Afroasiatic, languages), involves a distinction between singulative, plural or collective, and replacement marking (Dimmendaal 2000). Nouns referring to items usually occurring in pairs or in larger numbers, such as 'breast', 'fly', or ethnonyms, tend to take a singulative marker and are morphologically unmarked in the plural. In addition to plural (or collective) marking, nouns (in particular derived ones) tend to be inflected for number both in the singular and the plural. This three-way distinct is not attested in geographically more peripheral Nilo-Saharan zones, e.g., in Central Sudanic, Saharan, or Songai. Gender marking, though not widespread, is found as an inflectional feature of nouns in Eastern Nilotic, for example, and as a derivational property in the Southern and Western branch of Nilotic.

From a morphosyntactic point of view, Nilo-Saharan language groups spoken in an area ranging from northern Ethiopia and Eritrea across north-central Sudan and extending into Chad and Nigeria share typological features with Afroasiatic languages in Ethiopia. These include a basic constituent order whereby the verb occurs in final position, an extensive case marking system, verbal compounding (e.g., with 'say' or other types of light verbs, such as 'put' or 'do'), as well as the use of converbs as dependent verb forms in complex sentences, although not all properties are necessarily present in all groups. These common typological features to some extent may be due to areal diffusion as a result of long-term cultural contacts and corresponding patterns of multilingualism between speech communities in these areas. The Wadi Howar, also known as the Yellow Nile (a former river sanctuary and tributary to the Nile which connected the mountainous area in eastern Chad with the Nile Valley from about 8000 B.C. till about 1000 B.C.; cf. **Figure 1**), possibly constituted an important geographical condition for this cultural and linguistic diffusion (cf. Keding, 2000, for a discussion of the geomorphological and archaeological background; see also Amha and Dimmendaal, in press, for a discussion). The gradual extinction of this riverine system may have resulted in a diaspora of Nilo-Saharan languages from the Wadi Howar region in an eastern, western, and southern direction.

Ehret (2001: 202–209) has argued for the reconstruction of a series of case suffixes for the earliest stages of Nilo-Saharan. Such dependent-marking systems are indeed attested in a range of Nilo-Saharan groups between Chad and Eritrea, as pointed out above. Remnants of case marking are also attested in Central Sudanic languages, but not apparently in Koman or Songai. Reduced case marking systems, and, correspondingly, a more extensive verbal strategy of marking semantic roles like location, direction, and instrument, is found in Berta and Eastern Sudanic groups like Daju, Nilotic, Surmic, and Temein. Rather than having preverbal subjects, several languages belonging to these latter groups allow for postverbal subjects which are marked for case (the so-called 'marked nominative'). An interesting combination of head marking and dependent marking at the clausal level is found in the verb-initial Kuliak (Rub) languages (cf. König, 2002). For a number of Nilotic languages using the marked nominative strategy for postverbal subjects, it has been argued that this applies only to transitive predications, thus giving rise to ergative properties, as the object or the subject of an intransitive predicate precede the verb and are not marked for case. As shown by Reh (1996) for the Nilotic language Anywa (Anu), OVS and SV are but

Figure 1 Map of Nilo-Saharan languages.

one of several constituent order types allowed for in the language, alternatives being governed by pragmatic principles (e.g. active and less active participants, or participant orientation as against action orientation).

Pronominal subject (and occasionally object) marking, diathesis, causative, and pluractional marking are common morphological properties of verbs in Nilo-Saharan. Languages in the border area between Sudan and Chad, such as For or the Maban and Taman group, manifest complex morphophonemic alternations for consonants in their verb systems. Derivational morphology tends to be expressed mainly by way of suffixation, and by prefixation in Central Sudanic; the causative marker, however, involving a presumably cognate morpheme consisting of a high front vowel, tends to be expressed as a prefix in Central Sudanic as well as elsewhere in Nilo-Saharan.

The use of logophoric pronouns marking coreferentiality between argument positions across clauses and sentences is a feature of some Nilo-Saharan groups which is shared with Niger-Congo and Chadic as well as Omotic (i.e. Afroasiatic) languages. A universally uncommon anti-logophoricity marking is found in Western Nilotic Mabaan.

Nishida, Tatsuo (b. 1928)

M H Miyake, Aiea, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Tatsuo Nishida is best known for his work on the Tangut (Xixia, Hsi-hsia) language. Born in Ōsaka, he began his study of Tangut in 1950 by writing a paper on Tangut phonological reconstruction for Juntarō Ishihama, the pioneer of Tangut linguistics in Japan.

At Kyōto University in 1962, Nishida submitted a doctoral dissertation on Tangut, which he later revised as a two-volume monograph (1964–1966). This is his greatest work. It contains the first full-scale reconstruction of Tangut phonology, an overview of Tangut script and grammar, a dictionary of Tangut characters, and two decipherments of Tangut texts.

As an assistant and later full professor at Kyōto University, Nishida produced many articles and books on Tangut aimed at both scholarly and lay audiences. The most notable among them is *Hsi-hsia writing* (1967; rev. 1980; partially translated 1980). Nishida also served as a consultant on Tangut culture for the film *Tonkō* (Dun-Huang, 1988) and appeared in the documentary *Tonkō: Sono rekishi ga kataru roman* (Dun-Huang: the epic told by its history).

Although Nishida's phonological reconstruction of Tangut has not been widely accepted outside Japan, his analysis of most Tangut characters as semantic compounds without phonetic elements is still well within the mainstream of Tangut linguistics. However, such an analysis is at odds with DeFrancis's (1991) view of all writing systems as primarily phonetic and has been questioned by a few scholars such as Janhunen (1994).

In addition to his work on Tangut, Nishida has also written numerous books and articles on many other Sino-Tibetan languages, Tai-Kadai languages, and the extinct Khitan and Jurchen scripts. He has contributed to three book translations.

In 1976, Nishida proposed a genetic relationship between Japanese and Tibeto-Burman languages and explored this idea over the next several years. His attempts to branch out into Japanese historical linguistics have not been welcomed by specialists (e.g., Miller, 1980), who have overwhelmingly rejected his Japanese-Tibeto-Burman hypothesis.

Nishida, Tatsuo (b. 1928)

M H Miyake, Aiea, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Tatsuo Nishida is best known for his work on the Tangut (Xixia, Hsi-hsia) language. Born in Ōsaka, he began his study of Tangut in 1950 by writing a paper on Tangut phonological reconstruction for Juntarō Ishihama, the pioneer of Tangut linguistics in Japan.

At Kyōto University in 1962, Nishida submitted a doctoral dissertation on Tangut, which he later revised as a two-volume monograph (1964–1966). This is his greatest work. It contains the first full-scale reconstruction of Tangut phonology, an overview of Tangut script and grammar, a dictionary of Tangut characters, and two decipherments of Tangut texts.

As an assistant and later full professor at Kyōto University, Nishida produced many articles and books on Tangut aimed at both scholarly and lay audiences. The most notable among them is *Hsi-hsia writing* (1967; rev. 1980; partially translated 1980). Nishida also served as a consultant on Tangut culture for the film *Tonkō* (Dun-Huang, 1988) and appeared in the documentary *Tonkō: Sono rekishi ga kataru roman* (Dun-Huang: the epic told by its history).

Although Nishida's phonological reconstruction of Tangut has not been widely accepted outside Japan, his analysis of most Tangut characters as semantic compounds without phonetic elements is still well within the mainstream of Tangut linguistics. However, such an analysis is at odds with DeFrancis's (1991) view of all writing systems as primarily phonetic and has been questioned by a few scholars such as Janhunen (1994).

In addition to his work on Tangut, Nishida has also written numerous books and articles on many other Sino-Tibetan languages, Tai-Kadai languages, and the extinct Khitan and Jurchen scripts. He has contributed to three book translations.

In 1976, Nishida proposed a genetic relationship between Japanese and Tibeto-Burman languages and explored this idea over the next several years. His attempts to branch out into Japanese historical linguistics have not been welcomed by specialists (e.g., Miller, 1980), who have overwhelmingly rejected his Japanese-Tibeto-Burman hypothesis.

Niue: Language Situation

W B Sperlich, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Niue is a 260-sq-km coral island in the South Pacific, west of Tonga and about 2400 km to the northeast of New Zealand, of which it is a self-administered territory. Because of large-scale immigration to New Zealand, the population of the island has been decreasing over the last decades and stands currently at about 1500. English is the official language of Niue. Apart from English, Niuean (Niue) is the only language of Niue.

The sociolinguistic features of Niuean have undergone a radical shift, from its use as a purely local language to an endangered one that is being replaced by English. In pre-European and precolonial times, Niuean was the sole language on the island, and there was little opportunity for language contact due to the extreme isolation of Niue. Following colonization and missionary indoctrination of the Niuean population (originally estimated to be close to 10 000 islanders), both rapid depopulation (due to diseases and forced removal of labor – known as 'blackbirding' in the South Pacific) and language loss occurred. While Bible and hymn translations into Niuean established a highly formalized Niuean church language that survives to this day, the attendant education in English soon made the whole population bilingual.

The modern age, with its features of globalization and political and linguistic imperialism, further eroded the Niuean language use in favor of English – so much so that the younger generations now speak English as their first language and various degrees of Niuean as their second language. Still, contrary to popular perceptions, a 1995 survey of Niuean primary and secondary school children showed that over 80% wanted to keep Niuean as their first language but also wanted to be fully proficient in English. Education authorities in Niue, together with New Zealand language experts, are only now devising a formal curriculum for the Niuean language, while as a whole the Niuean education system follows that of New Zealand, where English is the main medium of instruction.

A sole radio broadcast channel on Niue plays mainly Western music, and the local television channel has only a 15-minute slot in Niuean. The local and intermittent newspaper is typically written in English, with some items translated into Niuean. As a consequence of not using Niuean as much as it could be used in both formal and informal domains, it is now an endangered language, with fewer than 1500 speakers left on the island. There are no monolingual speakers of Niuean left. With over 20 000 Niueans living in New Zealand, there have been some attempts to keep Niuean as their second and/or heritage language. Since Niue gained Internet access, there have also been some attempts to reconnect the Niue diaspora to its home island, and a number of websites promote the use of the Niuean language. However, a 2004 linguistic analysis of one such site casts doubt on the ability of cyberspace to revitalize a language in severe decline.

Niuean

W B Sperlich, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Niuean (Niue) is the language of Niue, a Pacific island and self-governing territory of New Zealand. Niuean belongs to the Tongic subgroup of Polynesian (with Tongan and Niuean as the only members). The language name is synonymous with the name of the island. It is derived from *niu-ee* ('coconut-see') and is considered by oral tradition to be the exclamation by the earliest arrivals from Tonga (no earlier than 2000 years ago, according to archaeological evidence), who were surprised to see many coconut palms growing on the island. While Niuean is clearly a Tongic language (i.e., the first and subsequent settlers arrived mainly from Tonga) there are also elements of Samoan, Pukapuka, and Cook Islands Maori embedded in the Niuean language. Borrowings since European contact, especially early on via missionary efforts and more recently via trade, tourism, and globalization, are on the increase, and the impact of English syntax on Niuean is already pronounced. However, conservative Niuean is a strict verb-initial (or predicate-initial) language, and depending on the definition of 'subject' and 'object' can be designated as either VSO or VOS. It has been argued that subjecthood in Niuean is not a syntactic category and that only a core predicate and arguments are the basic constituents of a sentence. Niuean is a split-ergative language (morphologically ergative, syntactically accusative). A canonical sentence with ergative (ERG) and absolutive (ABS) case marking is exemplified below:

Ne	kai	he	pusi	ia	e	moa
T	eat	ERG	cat	that	ABS	chicken

'that cat ate the chicken'

To better express the ergative case above, a more literal (but less idiomatic) translation would be via the English passive: 'The chicken was eaten by that cat.' Indeed, some linguists have compared the ergative case marking to that of passives, noting, however, that the ergative case is unmarked. Niuean does not have antipassives. Other syntactic areas of special interest include raising, instrumental advancement, topicalization, causatives, possession, reflexives, and noun incorporation. A special feature of Niuean morphology is reduplication. Furthermore, highly productive affixation allows complex morphological strings. The causative prefix *faka-* and the prefix *ma-*, which changes verbs into participles, are most common. Various degrees of lexicalization can make analysis difficult. The phonological inventory is simple in its use of only some 10 consonants (and no clusters) but is complex in its use of vowels, which are either short or long. Short vowels give rise to practically all combinations of diphthongs. Since the syllable structure is (C)V(V), there are many extended vowel sequences across morpheme boundaries, as for example in the complex word *faka-fe-haga-ao-aki*, where the sequence *-alaola-* is rearticulated.

Niuean as a conservative language is an important witness for historical linguists who work on proto-Polynesian and proto-Oceanic languages, as well as being an important sample language in typological and comparative linguistics.

Nivkh

G D S Anderson, Max Planck Institute, Leipzig, Germany, and University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Nivkh (Gilyak; *Ethnologue* code NIV) has perhaps 400 speakers (1991) out of an ethnic population of 4400 (as of 1996; G. A. Otaina) in East Siberia. There are two dialects, the Amur and the Sakhalin; the latter is subdivided into eastern and northern clusters. There are approximately 100 Amur Nivkh speakers out of a population of 2000 and 300 Sakhalin Nivkh speakers out of a total population of 2700 (as of 1995; M. Krauss). On Sakhalin Island, many Nivkh live in the villages of Nekrasovka and Nogliki. Along the Amur River, a number of Nivkh reside in Aleevka village. Nivkh is a true language isolate. Attempts to link it with other groups have never succeeded. The Nivkh still maintain their long-practiced traditional economies based on subsistence fishing supplemented by hunting and gathering.

Word initially, the velar nasal is common in Nivkh, as shown in Example (1) (Gruzdeva, 1998: 11–13, 24, 32):

(1)	ŋaarla 'very fat'	ŋaχ 'soft roe'
	ŋax '6'	ŋamk '7'
	ŋɨñk 'face'	pŋafqŋafq 'each other'

One of the hallmarks of Nivkh structure is the curious and characteristic system of morphologically conditioned stem-initial consonant mutation to mark a range of inflectional (and derivational) categories. In this regard, note the initial consonant in the word for 'head' in the following three Nivkh forms (Gruzdeva, 1998: 14):

(2)	kyxkyx tʲoŋr	ɨt zoŋr	čam dʲoŋr
	swan head	drake head	eagle head
	'swan's head'	'drake's head'	'eagle's head'

Like many languages of the Pacific Rim, Nivkh contrasts special portmanteau counting forms for nouns of various types (e.g., people vs. animals). Twenty six such classes of numerals have been reckoned for Nivkh by Panfilov (1962) and Krejnovich (1932). Compare the following examples for Amur and East Sakhalin dialects (Panfilov, 1962: 6–7; Gruzdeva, 1998: 24):

Nivkh

G D S Anderson, Max Planck Institute, Leipzig, Germany, and University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Nivkh (Gilyak; *Ethnologue* code NIV) has perhaps 400 speakers (1991) out of an ethnic population of 4400 (as of 1996; G. A. Otaina) in East Siberia. There are two dialects, the Amur and the Sakhalin; the latter is subdivided into eastern and northern clusters. There are approximately 100 Amur Nivkh speakers out of a population of 2000 and 300 Sakhalin Nivkh speakers out of a total population of 2700 (as of 1995; M. Krauss). On Sakhalin Island, many Nivkh live in the villages of Nekrasovka and Nogliki. Along the Amur River, a number of Nivkh reside in Aleevka village. Nivkh is a true language isolate. Attempts to link it with other groups have never succeeded. The Nivkh still maintain their long-practiced traditional economies based on subsistence fishing supplemented by hunting and gathering.

Word initially, the velar nasal is common in Nivkh, as shown in Example (1) (Gruzdeva, 1998: 11–13, 24, 32):

(1)	ŋaarla 'very fat'	ŋaχ 'soft roe'
	ŋax '6'	ŋamk '7'
	ŋɨñk 'face'	pŋafqŋafq 'each other'

One of the hallmarks of Nivkh structure is the curious and characteristic system of morphologically conditioned stem-initial consonant mutation to mark a range of inflectional (and derivational) categories. In this regard, note the initial consonant in the word for 'head' in the following three Nivkh forms (Gruzdeva, 1998: 14):

(2)	kyxkyx tʲoŋr	ɨt zoŋr	čam dʲoŋr
	swan head	drake head	eagle head
	'swan's head'	'drake's head'	'eagle's head'

Like many languages of the Pacific Rim, Nivkh contrasts special portmanteau counting forms for nouns of various types (e.g., people vs. animals). Twenty six such classes of numerals have been reckoned for Nivkh by Panfilov (1962) and Krejnovich (1932). Compare the following examples for Amur and East Sakhalin dialects (Panfilov, 1962: 6–7; Gruzdeva, 1998: 24):

(3)	**Amur**	**E. Sakhalin**	**Gloss**
	ñin, ñen	ñenŋ	'1 person'
	nɨr	nɨrŋ	'4 people'
	ŋax	ŋax	'6 people'
	ŋamk	ŋamk	'7 people'
	Amur	**E. Sakhalin**	**Gloss**
	ñɨñ	ñan	'1 animal'
	nur	nur	'4 animals'
	ŋax	ŋax	'6 animals'
	ŋamk	ŋamk	'7 animals'

Nivkh is typical of Siberian languages in its use of a range of grammatical and local/directional case forms. Among the oppositions found in Nivkh is a contrast between a dative and an allative case, as shown in the following examples (Gruzdeva, 1998: 20, 21) (NEG, negative; DAT, dative; IMP, imperative; REFL, reflexive; LOC, locative; ABL, ablative; ALL, allative; TERM, terminative; FUT, future; FIN, finite; PRED, predicative):

(4a) t^ha ɨkɨn-doχ t^haxta-ya
NEG elder.brother-DAT be.angry-IMP
'Don't be angry at (your) elder brother.'

(4b) ɲin-doχ p^h-vo-x
we-DAT REFL-village-LOC/ABL what
t^hamdid xer-ya
tell-IMP
'Tell us what is (going on) in your village.'

(4c) ɲi eri-rχa vi-nɨ-d^j-ra
I river-ALL/TERM go-FUT-FIN-PRED
'I shall go (up) to the river.'

(4d) tʃ-ɨtk haimŋaf-toɣo hunv-nd-ra
2-father old.age-ALL/TERM live-FIN-PRED
'Your father lived (up) to old age.'

One category marked morphologically in the Nivkh verb is reciprocal action. This is encoded by the prefix *v-* in Amur Nivkh and *v-/o-/u-* in Sakhalin Nivkh.

(5) v- or 'meet' v-aɣaɣ 'disturb each other'
o-smu 'love each other'

Also found is a syntactic means of indexing this category through the word *p^hŋafqŋafq* (REFL-friend. friend) 'each other,' a possible calque from Russian *drug druga*, etc.; the verbs in such sentences lack the reciprocal prefix (Gruzdeva, 1998: 32):

(6) imŋ p^hŋafqŋafq. lov-d^j
they each.other imitate-FIN
'They imitated each other.'

Subordinate clauses in Nivkh are generally marked by some kind of nonfinite, nominalizing, or adverbializing morphology. This is common in many Siberian and other Eurasian languages (Anderson, 2003). The following example is from Gruzdeva (1998: 50):

(7) ɨmk čo hak-vul
mother fish cut-TEMP.CV
p^h-ajmŋař-kiř rořˇ k^herai-d
REFL-husband-INSTRUMENTAL together talk-FIN
'Mother talked with her husband while cutting fish.'

Nöldeke, Theodor (1836–1930)

T M Potter, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Theodor Nöldeke, preeminent German philologist and historiographer, has afforded generations of specialists and generalists seminal scholarship on the ancient Semitic languages as well as documents from pre-Islamic and Islamic civilization. The remarkable work of this revered Orientalist has had the interest and admiration of the Semitist and the Classicist. Many of his writings remain basic resources in both fields. In work such as his pioneering *Geschichte des Korans,* Theodor Nöldeke served the needs of specialists as well as those of the general public. Not only a recognized scholar of prodigious talent and energy, he was also a visionary. He recognized and answered the immediate needs of fellow Orientalists and arguably became the primary force for future scholarly work, for instance, through his translations of key texts of Arab and Persian writers. His work can be grouped as the philology of Semitic languages and dialects, on the one hand, and the historiography of pre-Islamic and Islamic civilization, on the other. Shahīd describes Nöldeke as "the foremost Semitist of his time" (1977: 119). The measure of influence of the man Goshen-Gottstein called "the first great master of Aramaic dialectology" (1978: 170) can be seen in Garr's *Dialect Geography* (1985).

Nöldeke was born on March 2, 1836, in Harburg, Prussia – today, Harburg-Hamburg, Germany. Benefiting from his father's position and direction, he received a classical education. Childhood ailments influenced the young prodigy to focus early on the mastery of, first, modern and then, ancient languages – Arabic (Classical), Syriac, Turkish, and Persian. After he earned the prize of the French *Académie des Inscriptions* with his doctoral thesis on the history of the Qur'ān in 1859, he rewrote it in German for publication the following year at Göttingen under the title of *Geschichte des Korans*. He subsequently lectured at the prestigious universities of Göttingen, Kiel, and Straßburg. Despite lifelong infirmities, Nöldeke continued his ceaseless and prodigious work throughout the 94 years of his life (Hurgronje, 1982: 240–241). While many of his seminal works are periodically republished, the following may be considered among his most important:

- *Geschichte des Korans* (1860)
- *Beiträge zur Kenntnis der Poesie der alten Araber* (1864)
- *Grammatik der neusyrischen Sprache* (1868)

His work can be grouped as the philology of Semitic languages and dialects, on the one hand, and the historiography of pre-Islamic and Islamic civilization, on the other. Shahīd describes Nöldeke as "the foremost Semitist of his time" (1977: 119). The measure of influence of the man Goshen-Gottstein called "the first great master of Aramaic dialectology" (1978: 170) can be seen in Garr's *Dialect Geography* (1985).

Nöldeke was born on March 2, 1836, in Harburg, Prussia – today, Harburg-Hamburg, Germany. Benefiting from his father's position and direction, he received a classical education. Childhood ailments influenced the young prodigy to focus early on the mastery of, first, modern and then, ancient languages – Arabic (Classical), Syriac, Turkish, and Persian. After he earned the prize of the French *Académie des Inscriptions* with his doctoral thesis on the history of the Qur'ān in 1859, he rewrote it in German for publication the following year at Göttingen under the title of *Geschichte des Korans*. He subsequently lectured at the prestigious universities of Göttingen, Kiel, and Straßburg. Despite lifelong infirmities, Nöldeke continued his ceaseless and prodigious work throughout the 94 years of his life (Hurgronje, 1982: 240–241). While many of his seminal works are periodically republished, the following may be considered among his most important:

- *Geschichte des Korans* (1860)
- *Beiträge zur Kenntnis der Poesie der alten Araber* (1864)
- *Grammatik der neusyrischen Sprache* (1868)

- *Geschichte der Perser und Araber zur Zeit der Sasaniden* (1879)
- *Zur Grammatik des klassischen Arabisch* (1897)
- *Beiträge und Neue Beiträge zur Semitischen Sprachwissenschaft* (1904–1910).

As a well-respected scholar and colleague, Nöldeke figured prominently among fellow Orientalists like Bergsträsser, Brockelmann, and Lagarde. William Wright, the father of Arabic grammar in the west, sought recognition for and published Nöldeke's noteworthy translation (Nöldeke-Wright, 1884 [1981]). MacLean (1901 [1972]) dedicated his *Dictionary* to Nöldeke. In recent times Shahīd labels him "the equal of his contemporary, Ulrich von Wilamowitz-Möllendorf, the foremost figure in classical philology" (1977: 119). Lipinski (1997) relies upon a number of Nöldeke's unique contributions for his recent Semitic grammar.

Nominalism

G Klima, Fordham University, Bronx, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Nominalism is usually characterized in contrast to other two major theoretical alternatives concerning the ontological status of universals. According to this characterization, the nominalist position holds that universals are mere words (e.g., the word 'round'); in contrast, the conceptualist position would identify universals with concepts (e.g., the concept expressed both by the English word 'round' and by the Latin word 'rotundus'), and the realist position would claim universals to be universal things (e.g., the nonmental, nonphysical, abstract Form of Roundness itself).

Both historically and theoretically, there are a number of problems with this simple, indeed, simplistic conception. First, by these standards, no premodern author would qualify as a nominalist since all these authors held that our universal terms owe their universality to the universal concepts they express (thus, on this account all these authors would have to be classified as conceptualists), and no medieval author would count as a realist because they all denied the real existence of Platonic 'abstract entities' (although most medieval authors did posit universals both *in re*, as trope-like individualized forms such as the individual roundness of *this* billiard ball as opposed to the numerically distinct roundness of another one, and *ante rem*, as Divine Ideas, identical with God, who is not an 'abstract entity') (Klima, 2001). Accordingly, this conception leaves in obscurity the genuine theoretical differences of medieval nominalists and realists, who first distinguished themselves under these designations. However, as we shall see, clarifying these genuine theoretical differences, we can have a deeper understanding not only of what a genuinely

Nominalism is usually characterized in contrast to other two major theoretical alternatives concerning the ontological status of universals. According to this characterization, the nominalist position holds that universals are mere words (e.g., the word 'round'); in contrast, the conceptualist position would identify universals with concepts (e.g., the concept expressed both by the English word 'round' and by the Latin word 'rotundus'), and the realist position would claim universals to be universal things (e.g., the nonmental, nonphysical, abstract Form of Roundness itself).

Both historically and theoretically, there are a number of problems with this simple, indeed, simplistic conception. First, by these standards, no premodern author would qualify as a nominalist since all these authors held that our universal terms owe their universality to the universal concepts they express (thus, on this account all these authors would have to be classified as conceptualists), and no medieval author would count as a realist because they all denied the real existence of Platonic 'abstract entities' (although most medieval authors did posit universals both *in re*, as trope-like individualized forms such as the individual roundness of *this* billiard ball as opposed to the numerically distinct roundness of another one, and *ante rem*, as Divine Ideas, identical with God, who is not an 'abstract entity') (Klima, 2001). Accordingly, this conception leaves in obscurity the genuine theoretical differences of medieval nominalists and realists, who first distinguished themselves under these designations. However, as we shall see, clarifying these genuine theoretical differences, we can have a deeper understanding not only of what a genuinely

nominalist position was in the late Middle Ages but also what in general a genuinely nominalist position has to consist in, as well as the important conceptual connections such a position has to such broader issues as ontological commitment, abstraction, induction, essentialism, and the possibility of valid scientific generalizations.

Extreme Realism: Plato's Ideal Exemplars

The problem of universals originated with Plato's answer to the question of how universal knowledge (e.g., our knowledge of geometrical theorems) of a potential infinity of individuals is possible. Plato's answer in terms of his theory of Forms involves the idea of regarding individuals of the same kind as copies of an original exemplar or archetype and assuming that our understanding has some direct access to this exemplar. Clearly, if I can read today's news on the printer's printing plates, then I do not have to buy the copies at the newsstands to get my news. Likewise, knowing that the form of all triangles, after which all triangles are modeled, has three angles equal to two right angles, I know that all triangles have the same property. Thus, Plato's answer is obviously a good answer to the question of the possibility of universal knowledge. However, this answer raises more problems than it solves. If the exemplar is not one of the copies, yet it has to be like the copies (given that the copies all have to be like it), then what sort of entity is it? In fact, this is precisely the basis of the most famous argument against Plato's theory, the Third Man (Wedberg, 1978). For if the exemplar has to be of the same sort as its copies, it can be grouped together with its copies into the same kind. However, if for a group of individuals of the same kind there always has to be a common exemplar, and nothing can be its own exemplar, as Plato's theory claims, then there has to be another exemplar for the exemplar and its copies taken together. Since this reasoning can be repeated indefinitely, we have to conclude that for a given set of copies there would have to be an infinity of exemplars, contrary to the theory's explicit claim that there can only be one such exemplar. Therefore, since the theory as stated entails inconsistent claims, it cannot be true in this form.

Moderate Realism or Conceptualism: Aristotle's Universals

Prompted by such and similar inconsistencies, Aristotle famously rejected Plato's Forms and provided a radically different sort of answer to Plato's original question concerning the possibility of universal knowledge. Plato's idea was that this sort of knowledge is possible because of the human soul's prenatal access to the Forms serving as the common exemplars of all sorts of particulars the soul comes to experience in this life and the soul's ability to recollect these Forms and their properties prompted by these experiences. In contrast, Aristotle's idea was that we can have this sort of knowledge from experience in this life. To be sure, the finite number of experiences we can have in this life with individuals of the same sort can never justify universal knowledge claims that cover a potential infinity of such individuals. However, if our cognitive faculties enable us to recognize a common pattern that equally characterizes any possible individual of the same sort, then even this finite number of experiences may enable us to make valid generalizations covering all possible individuals of the same sort. Using the previous analogy, in this case I do not have access to the printer's plates (if there is any such thing at all, which need not be the case if copies can 'self-reproduce,' as in photocopying); I can only collate a number of variously smudged, incomplete newspapers, from which, nevertheless, I am able to extract their common content so that I will know the news any other copy of the same issue may carry even before actually checking it. This is the idea Aristotle worked out in his theories of abstraction and induction.

The Moderate Realism/Conceptualism of Medieval Aristotelians

According to Aristotle and his medieval interpreters, human understanding is characterized by two intellective powers or faculties, namely the active intellect (nous poietikos, *intellectus agens*) and the receptive intellect (nous pathetikos, *intellectus possibilis*). Due to the obscurity of Aristotle's formulations, in the Middle Ages there was much debate about the makeup of these faculties, namely whether they are material or immaterial, and whether they existed as individualized powers of individual human souls or, rather, as separate substances connected to individual human souls to carry out their intellectual operations (pretty much as mainframe computers are connected to their terminals). However, regardless of these differences, there was quite general agreement concerning the function of these intellective powers (whatever they are in themselves) and how they can produce universal knowledge without having to 'look up to' or 'recollect' Platonic Forms. The active intellect has the function of producing simple, universal concepts (i.e., universal representations of individuals) from their singular representations provided by

the senses. The receptive intellect, on the other hand, receives these universal representations for further processing, combining them into more complex concepts and judgments by means of complexive concepts, the so-called syncategorematic concepts ('syncategoremata'), and using these judgments in reasoning.

Abstraction, Induction, and Essentialism

In the process of abstraction, the active intellect forms a common concept by considering the multitude of experiences of particulars of the same kind, disregarding what is peculiar to each while focusing on what is common to all. The common concept retained in the receptive intellect is a mental representation that represents the individuals it is abstracted from only with respect to what commonly characterizes them all. Accordingly, the same mental representation will naturally represent in the same respect not only those individuals that it is abstracted from but also other individuals of the same kind – that is, individuals that resemble the observed ones precisely in the same respect in which the abstracted concept represents the observed individuals. Therefore, if the receptive intellect forms a judgment with this concept in which the predicate belongs to the particulars that fall under this concept on account of falling under this concept, then it is able to produce a valid scientific generalization by induction – that is, by reasoning in the following way: This observed S was P, and that observed S was P, and so on for all observed S's; therefore, in general, every S is P. Obviously, this inference is valid (not formally, but materially) only if an S is essentially and not merely coincidentally P – that is, if an S is P on account of being an S so that any S is necessarily P, as long as it is an S (and if it is also essentially an S, then it is necessarily an S, and hence also a P, as long as it exists). This is precisely why this inference requires the multitude of experiences, namely to ensure that the observed S's have been P not by mere coincidence but precisely on account of being S's. However, if this inference is valid, then it obviously provides a good answer to Plato's original question (concerning the possibility of universal knowledge) without resorting to Plato's universal Forms.

The Ontological Commitments of Moderate Realism

However, the previous conception may still involve an enormous amount of ontological commitment; admittedly, not to Platonic universal Forms but to individuals of a rather strange sort, the individualized forms of individual substances. If all our common terms are applicable to individual things on account of our common concepts, and we gain these concepts by abstraction from the individualized forms or properties that sort individuals into various kinds, then apparently there are as many individualized forms in an individual substance as there are true common predicates of it. (Yet, this conception need not make individual substances into mere congeries of individualized forms, in the vein of modern trope theories. On this conception, individual substances are the primary units of reality that account for the individuation of individualized forms, and not the other way around (cf. Campbell, 1997; Daily, 1997).) In this moderate realist view, commonly endorsed by medieval authors of the 13th century (e.g., Thomas Aquinas), the world is a world of individuals without 'universal entities,' but it is populated by all sorts of nonsubstantial particulars, serving as the individualized *significata* of our common terms. The universals of this world, then, are the common terms of our language as well as the concepts they express, and the individualized forms as-conceived-in-a-universal-manner by means of these concepts (i.e., as-existing-in-the-mind as the direct objects of these concepts) (Klima, 1999). To be sure, these authors were able to reduce the ontological commitment of their theories by two fundamental semantic strategies: the distinction of several senses of 'being' and the identification of the semantic values of various terms.

On the first strategy, ontological commitment simply becomes ambiguous among different kinds of entities credited with different degrees of reality corresponding to different senses of 'existence' or 'being' (such as being in reality, *esse reale*, and being in the mind, *esse rationis*; cf. Klima, 1993) – a move generally rejected by nominalists.

On the second strategy, however, ontological commitment is reduced even within the same domain of entities. For instance, since two billiard balls A and B are similar in shape, the moderate realist view is apparently committed not only to the individualized roundness of A and the individualized roundness of B but also to the individualized similarity of A to B and to the individualized similarity of B to A. However, several moderate realist authors would argue that nothing prevents us from saying that the roundness of A is the same thing as the similarity of A to B, merely conceived differently, by means of a different concept (Henninger, 1989; Brower, 2001).

Late Medieval and Modern Nominalism

This strategy actually anticipates the more radical reductionist program of William Ockham and his

14th-century followers, such as John Buridan, Albert of Saxony, Marsilius of Inghen, and in general the late medieval nominalist tradition of the *via moderna*. These nominalist authors agreed with their moderate realist counterparts in positing a world consisting only of individuals and identifying universals with universal terms of written and spoken languages, which owe their universal mode of representation to universal concepts of the human mind, interpreted as singular mental acts representing their singular objects in a universal manner. However, they denied even the 'diminished' existence of universals as universal objects of these mental concepts admitted by moderate realists, and they reduced the number of really distinct categories of singulars to two or three, admitting distinct entities only in the categories of substance, quality, and possibly quantity. (Ockham, for example, identified substance with quantity, whereas Buridan argued against their identification.)

To be sure, using their own eliminative strategy of identifying the semantic values of linguistic items in different linguistic categories, the moderate realists could in principle achieve the same degree of ontological parsimony. However, for them this was to be achieved separately, based on metaphysical considerations. Their semantics demanded positing as many different types of semantic values for their terms as there are different linguistic categories, although it was possible for them to decide on the basis of further metaphysical considerations about the identity or nonidentity of these semantic values. In contrast, the nominalists had the principles of ontological reduction (i.e., eliminating unwanted ontological commitment) 'built into' their semantic principles (Klima, 1999). The reductionist program of the nominalists was devised to show that it is possible to have a sufficiently 'fine-grained' semantics without a complex ontology by 'moving' the requisite distinctions from (a full-fledged or 'diminished') reality to the conceptual structures posited in the mind.

For example, in contrast to the moderate realist interpretation of similarity alluded to previously, in the nominalist approach there is no metaphysical question of whether the relation signified by the term 'similar' is identical with its foundation, for example, the roundness of ball A. The signification of 'similar' is not construed in the same way in the first place. Instead of assuming that in 'A is similar to B' this term signifies A's similarity to B, an extramental entity that may or may not be distinct from the roundness of A, the nominalists would say that this term simply signifies A in relation to B, on account of the relative (connotative) concept whereby we conceive of A in relation to B. Therefore, even if we do have the obvious semantic difference between the absolute term 'round' and the relative term 'similar,' this semantic difference need not be accounted for in terms of a bloated ontology of distinct extralinguistic correlates of these terms because the relevant semantic distinctions can be made with reference to conceptual distinctions in the mind.

Following this nominalist strategy, once we have identified a basic 'vocabulary' of simple concepts that only commit us to entities in the 'permitted' ontological categories, any further apparent ontological commitments of our language can be eliminated by means of nominal definitions, which show how the semantic features of linguistic items carrying such apparent ontological commitment can be accounted for in terms of an implicit conceptual structure that can be explicated by means of the basic vocabulary carrying commitment only to permitted entities. Indeed, this strategy of eliminating ontological commitment by means of nominal definitions explicating this implicit conceptual structure foreshadows the similar strategy of elimination by paraphrase characteristic of all modern nominalistic programs.

Thus, in this approach, and this is the gist of medieval nominalism in general, a sufficiently fine-grained semantics for natural language is achieved by mapping linguistic constructions onto sufficiently rich conceptual structures in a mental language (comparable in its role to the contemporary 'language of thought hypothesis'), which in turn can be mapped onto a parsimoniously construed reality without any loss of semantic distinctiveness.

Modern nominalistic programs, such as the program promulgated by Goodman and Quine (1947), apply the same basic strategy, but without the medievals' appeal to a mental language, by introducing the explicit ontological commitment of a primitive vocabulary and by eliminating any further apparent commitment (e.g., to such 'abstract entities' as numbers) by providing suitable paraphrases of relevant linguistic items (e.g., numerals) in terms of this primitive vocabulary. Indeed, in this program, Platonistic descriptions of language in terms of linguistic types are replaced by a nominalistic syntax treating of tokens, such as singular inscriptions. (In fact, medieval nominalists also formulated their logical theories in terms of token-phrases (Klima, 2004a).) The successful paraphrase then shows that there is no need to assume the existence of the putative entities apparently required by the semantic features of the phrases that appeared to carry commitment to them, so nominalists are entitled to get rid of them by one swoosh of Ockham's razor.

Nominalism, Antirealism, and Skepticism

Yet, despite customary charges and modern tendencies to the contrary, the 'reductionist' program and the corresponding strategy of medieval nominalism did not necessarily result in metaphysical antirealism, conventionalism, or skepticism. Medieval nominalists typically regarded concepts as naturally representative of a world of individuals presorted into natural kinds and not sorted into these kinds by our concepts and/or linguistic conventions. Thus, they maintained an essentialist metaphysics, and so the scientific knowability of a mind-independent reality, yet without any ontological commitment to (whether subsistent or inherent) universal essences distinct from their individuals. Whether they could consistently do so is a further issue, which bears direct relevance to contemporary considerations concerning ontological commitment and metaphysical essentialism. Plato's problem of the possibility of universal knowledge still remains a problem for nominalists: Once they have rejected the moderate realists' distinct individualized forms, which in the moderate realist conception are precisely the items in reality that serve as the foundation for the abstraction of our universal concepts, the nominalists still have to provide a plausible story about how universal concepts can be abstracted from observed singulars (and hence how they can apply even to previously unobserved singulars), unless they want to give up on the possibility of universal knowledge in the classical sense altogether (Klima, 2004b, 2005).

Nominalization

M Koptjevskaja-Tamm, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Nominalization proper means 'turning something into a noun' (Comrie and Thompson, 1985), and refers both to the corresponding processes or operations and to their results. Nominalization covers a broad range of transpositional phenomena, where transposition, in turn, refers to word-class-changing operations (Haspelmath, 2002). Often applied without clear criteria and definitions, the term has been grossly misused. A clear definition of nominalizations and any serious attempts to approach them cross-linguistically should take into account at the least the following parameters:

Nominalization

M Koptjevskaja-Tamm, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Nominalization proper means 'turning something into a noun' (Comrie and Thompson, 1985), and refers both to the corresponding processes or operations and to their results. Nominalization covers a broad range of transpositional phenomena, where transposition, in turn, refers to word-class-changing operations (Haspelmath, 2002). Often applied without clear criteria and definitions, the term has been grossly misused. A clear definition of nominalizations and any serious attempts to approach them cross-linguistically should take into account at the least the following parameters:

- What expression types are turned into a noun?
- What are the meanings of the resulting expressions?
- What does turning into a noun really mean, i.e., in what sense is the resulting expression a noun?
- How regular is this process, e.g., is it derivational or inflectional?
- Do the resulting expressions show mixed properties (partly nominal, partly stemming from the base expression type)?
- What are the functions of the resulting expressions?

The next section will show how most of these parameters work for one particular kind of nominalizations that has received most attention within various linguistic theories and has been intensively studied cross-linguistically – action nominals. This is followed by a sketch of some other nominalization phenomena. The final section will give a brief survey of the functions in which nominalizations are typically used and point out possible connections between these uses and the morphosyntactic properties of the corresponding nominalizations. Throughout the chapter the main emphasis will be on the phenomena themselves, rather than on the various attempts to present a formal analysis of them.

Action Nominals and Action Nominal Constructions

Action nominals (*nomina actionis*, AN), such as *running, arrival, reading,* and *conquest* are in some reasonably productive way derived from verbs, either derivationally or inflectionally. Broadly speaking, they refer to situations and not only to actions, as the name might imply (Comrie and Thompson, 1985; Koptjevskaja-Tamm, 1993, 2003, 2005). Action nominals head action nominal constructions (ANCs) that may also contain expressions referring to the participants in the situation designated by its head, most often serve as arguments (complements) to predicates and refer to events, facts, and propositions, to use the semantic taxonomy launched by Vendler (1967). For instance, predicates *to assert* and *to be unlikely* combine with ANCs referring to propositions (*The collapse of the country's economy is unlikely*), the verbs *to know, to regret,* and to *lead* take ANCs referring to facts (as in *The enemy's destruction of the city led to a complete collapse of the country's economy*), while the verbs *to hear* and *to go on* take ANCs referring to events (*The singing of the Marseillaise went on for hours*).

ANs are either 'full-fledged' nouns or at least occur in typical nominal positions and show inflectional properties, such as case inflection, and/or combinability with adpositions typical of nouns. There is, on the whole, relatively little consensus in terminology used for what is called 'ANs' and 'ANCs' here. Thus, 'verbal nouns,' 'gerunds,' 'nominalizations,' 'masdars,' 'infinitives' often, though not necessarily, refer to ANs (Koptjevskaja-Tamm, 1993: 22–43). Grimshaw (1990) used the term 'complex event nouns,' opposed to 'simple event nouns' (or act nouns), such as *announcement*. Action nominals, as defined here, are robustly attested cross-linguistically, though not everywhere. Thus, they are as a rule absent from Australian and most North American Indian languages.

In their semantics and discourse behavior, action nominals combine verbal and nominal properties and occupy an intermediate position between typical nouns and typical verbs. Thus, both *John's singing* and *John sings* can describe one and the same event involving the same participant, and the same goes for *the enemy's destruction of the city* and *the enemy destroyed the city.* However, ANCs, as opposed to normal finite clauses, merely name situations and occur in functions typical of NPs, for instance, as arguments to predicates. On the other hand, they differ from typical nouns that refer to things, persons, places, and other more or less concrete objects. Also, action nominals take arguments more or less like the corresponding (finite) verbs do. Nouns normally do not take arguments, even though this might be doubtful for relational nouns, such as kinship terms or words for body parts.

Morphosyntactically, ANs often show a mixture of verbal and nominal properties and provide, therefore, good examples of mixed categories (Lefebvre and Muysken, 1987; Spencer, forthcoming). Thus, in the example *John's repairing the house so quickly [came as a big surprise],* the AN *repairing* combines with its 'object' *the house so quickly* and with the adverb in a typically verbal way, as in the corresponding finite clause *John repaired the house* so quickly. Moreover, the AN in the same construction can be negated and/or combine with auxiliaries, again in the way typical of verbs, e.g., *John's having not repaired the house*. Its 'subject,' however, appears with the *'s*-marker, typical of adnominal dependents (possessors). The same action nominal may also build constructions that look very much like 'normal' NPs with underived nouns (cf. *John's quick repairing of the house* and *John's accurate map of the city*).

The question that has attracted most research is whether and how action nominals can combine with expressions referring to the participants in the situations designated by them, primarily with S (as *John* in *John's running*), and with A and P (as *the enemy* and *the city* in *the enemy's destruction of the city*). There

is a long tradition in distinguishing between derivational nominalizations (like *conquest, refusal,* and *arrival*) and inflectional nominalizations, like English gerunds (Chomsky, 1980). According to this tradition, derivational nominalizations are said to be lexically restricted; they may have unpredictable semantic and syntactic properties as compared to the verbs they are derived from, as well as idiosyncrasies in formation; they also combine with their dependents in exactly the same way as prototypical nonderived nouns. Inflectional nominalizations are described as being formed from any verb in a regular way, their meaning is completely predictable, and they retain a good portion of verbal syntactic properties. This distinction is, however, of little use for a cross-linguistic comparison, because it is precisely action nominals that in many languages pose serious problems for a clear-cut distinction between derivational and inflectional forms, in that the various criteria suggested for distinguishing inflection and derivation clash when applied to them (Comrie and Thompson, 1985; Koptjevskaja-Tamm, 1993: 263–266; Haspelmath, 1996). A part of the difficulties with distinguishing between derivation and inflection can stem from diachronic processes; for instance, English gerunds started as derivational, but have gradually become inflectional forms (Miller, 2002: 315–350).

Cross-linguistically ANCs may be classified in accordance with their sentence-likeness and/or NP-likeness, i.e., with the degree to which the relations between an AN and its arguments are encoded in the same way as verb-arguments relations in finite clauses or as head-dependent relations in NPs (primarily, the possessee-possessor relations, *see* **Possession, Adnominal**), respectively. The typology of ANCs assumed here is based on marking of the arguments themselves (by means of case-marking and adpositions) as a primary parameter, in a few cases supplemented by head-marking as an additional parameter (for details cf. Comrie and Thompson, 1985; Koptjevskaja-Tamm, 1993, 2003, 2005). One and the same language often has several ANC types, not necessarily possible for one and the same AN.

Thus, in English *John's running* and *the enemy's destroying the city* illustrate the Possessive-Accusative type: S and A are treated as possessors, while P retains sentential marking (in this case, the absence of any overt marker). *The destruction of the house by the enemy* belongs to the Ergative-Possessive type, where S and P are treated as possessors, while A is treated differently. In this particular example, A looks like the agent in passive sentences; this is a cross-linguistically usual, but not a necessary option. A may be treated as other peripheral NPs. Finally, in *the enemy's destruction of the city,* all major arguments are treated as possessors, this is the Double-Possessive type. While English has two distinct possessor forms and possessor positions that can differentiate between the A and the P, most languages with this ANC type use one and the same form for both, as shown by ex. (1) from the Austronesian language Tukang Besi (Tukang Besi South). This type is cross-linguistically relatively rare, compared to the other ANC types.

(1) te basa-'a nu La Petrus nu boku
CORE read-AN POSS PROP.M Peter POSS book
'Peter's reading of the book.' (Mark Donohue p.c.)

In a number of languages ANCs are built according to the Sentential type: S, A, and P receive the same dependent-marking as in the finite clause. In ex. (2) from Tamil, the A and the P appear in the unmarked form both in the finite clause (2a) and in the ANC (2b), while possessors normally take the genitive case.

(2a) coomu tampikki paŋam
Somu younger.brother.DAT money
kuɽu-tt-aaru

give-PAST-AN surprising be.PAST.3SG.N
'It was surpring that Somu gave younger brother the money.' (lit. 'Somu's giving the money to the younger brother was surprising.') (Asher, 1982: 110)

In a number of languages, action nominals can never combine with both A and P within one and the same construction. Sometimes there are strategies for expressing both A and P at the same time without, however, making both of them syntactically dependent on the AN. Thus, the English ANC *John's repairing the house* may be rendered by constructions like *John's house-repairing* (where the P and the action nominal build a compound), *the repairing of the house that John did,* or *the repairing that John repaired the house*. The latter option is illustrated by (3) from Yoruba. The cover term for this somewhat heterogeneous class is the Valency-Lowering type; the common denominator is the reduced valency of an AN compared to that of the verb. This is, of course, well in line with the behavior of more typical nouns that hardly ever take two arguments.

(3) rírà tí Olú ra aso
buy.AN REL Olu buy dress
'Olu's buying of the dress' (Ayo Bambgbose p.c.)

These major patterns can be ordered as a scale from sentence-like constructions to those that have a

Figure 1 Scale of sentence-like and NP-like dependent-marking in the major ANC patterns.

Figure 2 Hierarchy of sentential vs. NP-like syntactic means in ANCs.

NP-syntax, with intermediate patterns combining elements of both sentences and NPs (Figure 1).

Cross-linguistic variation in ANC structure is, thus, severely restricted in at least two respects. First, arguments differ systematically in their proneness to retain sentential marking. Second, the three kinds of overt means for encoding head-dependent relations – dependent-marking, head-marking (agreement), and word order – form a hierarchy that predicts which combinations of nominal and sentential properties are possible (cf. Figure 2). For instance, of the two arguments in transitive ANCs, the one most likely to lose its sentential dependent-marking is the A; in addition, the A never retains its head-marking. To a certain degree, though not completely, this corresponds to the assumption found in various theories that finiteness of a clause and the properties of its subject are crucially related; since ANCs are not finite, their 'subjects' may be or even should be different from those in finite clauses.

The data in Koptjevskaja-Tamm (1993) show that there is also a correlation between the different ANC types, on the one hand, and the presence vs. absence of other typical verbal vs. nominal features in their head, such as the ability to express tense/aspect distinctions (cf. ex. (2) from Tamil), voice and negation, and the ability to combine with adverbs/adjectives. More systematic research is, however, needed here. Also, even though ANs generally pose problems for the derivation/inflection-distinction, the 'extreme' ANC types do show a high degree of consistency among the different criteria. Thus, action nominals with a sentence-like syntax normally involve generally applicable and regular markers and show semantic transparency, while action nominals with a nominal syntax often manifest various idiosyncrasies typical of derivation (cf. also Haspelmath, 1996: 57–58).

Other Kinds of Nominalization and Nominalization-Related Phenomena

Expressions That Can Be Turned into Nouns and the Meanings of the Resulting Expressions

Some languages have verbal nouns which refer to the way, or manner, of performing the action denoted by the base verb – mode, or manner nominals (*nomina modi*), distinct from action nominals, e.g., in Amharic *akkiyahed* 'the way of going' vs. *mohed* 'to go, going,' or in Turkish *yürü-yüş* 'the way of walking.' Verbs may also be turned into nouns that name one of their arguments, or various circumstances concomitant to the situation designated by them. The former class includes agentive nouns (*nomina agentis*), or subject nominalizations, e.g., *singer, employer,* object nouns, e.g., *employee,* and result nominalizations, e.g., *agreement* (as in *The agreement they signed was submitted in four copies*). The latter includes instrument nominalizations, e.g., *sharpener,* locative nominalizations and reason nominalizations, e.g., derivations with the suffixes *-vvik* resp. *-ssut* in West Greenlandic (Inuktitut, Greenlandic), such as *puisinniarvik* 'place for hunting seal' and *kamassut* 'reason for anger' (Fortescue, 1984: 319).

Adjectives may also be turned into nouns, e.g., state/property nominalizations such as *stupidity* and *redness*. Occasionally words from other word classes can be turned into nouns. Languages may have much more fine-grained semantic distinctions in nominalizations than what is presented above. It is also often the case that one and the same nominalization marker can produce different meanings, e.g., the English suffix *-er* used for deriving both agent and instrument nouns.

In all the examples considered so far, a word of one particular class (verbs, adjectives) has been turned into a noun – these are instances of lexical nominalization. In clausal nominalizations, on the other hand, it is the whole finite clause that gets nominal inflectional features, while its head cannot be considered a noun (Comrie and Thompson, 1985: 392), as in (4) from Imbabura Quechua (Quichua, Highland, Imbabura).

(4) Pedro ya -n [ñuka Agatu-pi kawsa-ni]-ta
Pedro think-3 I *Agato-in live–1-ACC*
'Pedro thinks that I live in Agato.' (Cole, 1982: 43)

More specifically, the verb in such nominalized clauses normally retains all its verbal characteristics (such as person and number inflection) and does not occur with nominal derivational affixes, although the whole nominalized clause may be more or less similar to an NP. Clauses may be nominalized in different ways, for instance by taking an article or by attaching nominal inflectional suffixes to finite verbs, such as

the accusative case in (4). In the latter case, the verbs inflect in the same way as nonderived nominals, but there may still be arguments against considering them lexical nominalizations. Clausal nominalizations are quite widespread across North American Indian languages, which, as a rule, lack action nominals, and across Tibeto-Burman languages (Matisoff, 1972).

In a few cases, however, the distinction between lexical and clausal nominalizations is difficult to draw. Or rather, nominalization markers may be 'omnivorous' in attaching to expressions of structurally different kinds – words, word combinations, clauses. One reason for this may lie in diachronic processes; thus, it has been suggested for several languages (e.g., for Newari in Genetti, 1991 and for Navajo in Mithun, 2002) that nominalizers, case morphology, and adpositions have been extended from lexical items to clauses.

What Does Turning into a Noun Really Mean?

One of the criteria for ANs given earlier in this article is that they should at least occur in typical nominal positions and show inflectional properties, such as case inflection, and/or combinability with adpositions, typical of nouns. However, ANs often show only a subset of nominal inflectional and combinatorial properties; thus, they normally lack number distinctions.

Individual inflected forms of action nominals, often used in particular functions, may gradually detach themselves from the original paradigm and become nonfinite verb forms on their own. Thus, infinitives in many languages originate as purposive action nominals, i.e., action nominals with the dative or allative marker (Haspelmath, 1989), e.g., the Slavic infinitive ending *-ti* is the dative case of the earlier verbal noun. Adpositional or case forms of verbal nouns are a frequent grammaticalization source for converbs, i.e., nonfinite verbal forms used in adverbial subordination (Haspelmath, 1995). Such processes can sometimes result in a set of forms that all look like inflected forms of one and the same verbal noun. Synchronically, however, this analysis is hardly appropriate, and the term 'nominalization' is not applicable to such phenomena. Thus, typically, the whole paradigm is significantly reduced compared to the normal nominal paradigm; in addition, the inflected forms may have very specialized meanings not always easily deducible from the 'normal' case meanings. Examples (5) and (6) from Finnish illustrate the inflected (adessive, abessive, illative, and elative) forms of what is labeled 'third infinitive' in the Fennicist tradition. While the forms in (5) should rather be classified as converbs, the forms in (6) correspond to the typical infinitival uses.

(5) Finnish (Ylikoski, 2003: 204, 212)
Pekka tek-i rikokse-n. . .
*Pekka make-*PAST.3SG *crime-*GEN
'Pekka committed a crime. . .'

(5a) juo-malla olut-ta.
*drink-*CONV (='INF3.ADE') *beer-*PART
'by drinking beer.'

(5b) juo-matta olut-ta.
*drink-*CONV (='INF3.ABE') *beer-*PART
'without drinking beer"

(6a) Pekka rupes-i juo-maan olut-ta.
*Pekka begin-*PAST.3SG *drink-*'INF3.ILL' *beer-*PART
'Pekka began drinking beer.'

(6b) Pekka lakkas-i juo-masta olut-ta.
*Pekka case-*PAST.3SG *drink-*'INF3.ELA' *beer-*PART
'Pekka began drinking beer.'

Typical infinitives may in turn be further 'nominalized,' e.g., by attaching a definite article, and start being used as action nominals, often acquiring more and more nominal properties. Ex. (7) shows that infinitives combined with definite articles in German and Italian may take P (object) in the possessive form and be modified by adjectives. This completes thus 'a full cycle of noun-to-infinitive-to-noun' (Disterheft, 1980; Gaeta, 1997).

(7a) Italian
Sento il mormorare somesso del mare
*hear.*PRES.1SG *the whisper.*INF *soft of.the sea*
'I hear the soft whisper of the sea'

(7b) German
Das schnelle Zerstören der Stadt
*the.*N *rapid destroy.*INF *the.*GEN.F.SG *city*
war notwendig.
*was.*3SG *necessary*
'The rapid destroying of the city was necessary.'

There has been surprisingly little discussion in the literature of the criteria that can be used for deciding when 'something has been turned into a noun' and for distinguishing nominalizations from related phenomena (for some attempts cf. Noonan, 1985; Koptjevskaja-Tamm, 1993: 33–45; Haspelmath, 1995; Ylikoski, 2003). This is also, probably, the domain where different local traditions particularly diverge from each other and where consistent research in terminology is particularly urgent. To quote one example, Nordlinger (2002) argued that 'nominalized verbs' in the Australianist linguistic tradition are not nominalized in the usual sense of the word, i.e., have not been turned into nouns. Even though they may attach some (but not all) of the case markers (e.g., the allative case marker in ex. (8)), they cannot occur in syntactic positions typical of nouns, such as arguments. Rather they function as modifiers

– either as heads of relative clauses modifying a head noun, or as adverbial modifiers.

(8) Warlpiri (Simpson, 1988: 205, ex. 2)

Ngarrka-ngku	marlu	pantu-rnu
man-ERG	*kangaroo*	*spear*-PAST
[marna	nga-rninja-kurra].	
grass	*eat*-NMLSR-ALL	

'The man speared the kangaroo while it was eating grass.'

Functions of Nominalizations Nominalizations can be used in many ways, but two groups of functions are particularly salient cross-linguistically – as non-main (dependent) predicates in a sentence and as a part of analytical or periphrastic verb forms.

There is a considerable cross-linguistic variation in how much and where nominalizations are involved in dependent predication. Some languages have a more or less strict division of verb forms into those that can be main predicates and those that cannot. In many of those action nominals are among the predominant forms used in complementation, e.g., in Cuzco Quechua (Quechua, Cuzco), Tamil, Daghestanian languages. However, even in such languages, the exact range of functions attributed to action nominals and to action nominal constructions is to a high degree language specific and depends, primarily, on what other verb forms there are in the language. In other languages, action nominal constructions compete both with other types of nonfinite complements and with finite complementation. On the whole, determining where action nominal constructions are used (as a less frequent alternative to another major complementation type, as a regular and even the only complementation type) is far from evident, and the cross-linguistic variation here is enormous. Thus, in English, *to stop* is one of the verbs that obligatorily take gerunds as complements, e.g. *to stop reading/*to stop to read* (in the intended meaning), while its close synonym *cease* takes only infinitives (*to cease to read*). In Russian, the verb *perestat'* 'to stop' cannot take action nominals as complements, the only option for the latter being infinitives, e.g., **perestat' čtenie/perestat' čitat.'* Curiously, its close synonym *prekratit,'* as well as most of the other phasal verbs, allow combinations both with action nominals and with infinitives, e.g., *prekratit' čtenie/prekratit' čitat.'* Still, in contrast to English, no predicates in Russian obligatorily take action nominals as complements.

Action nominals in various case forms and/or combining with various adpositions are also frequently used in adverbial functions, e.g., *after/before John's arrival…*, and as adnominal attributes, e.g., *a knife for cutting apples*.

In many languages, subject and object nominalizations constitute the main relativization strategy, i.e., they function often as adnominal clausal modifiers. In ex. (9) from the Tibeto-Burman language Kham (Parbate, Western), the nominalizer *-o* derives a subject nominalization, which is used as a noun in ex. (9a) and as a subject relative clause in ex. (9b). Ex. (10) shows how the same marker may produce object nominalizations, which again can function both as nouns and as adnominal modifiers.

(9a) ba-o-rə
go-NMLZ-PL
'those who went'

(9b) ba-o mi:-rə
go-NMLZ *person*-PL
'the people who went'

(10a) o-ra-e-o-rə
3S-3P-give-NMLZ-PL
'those to whom he gave it'

(10b) [no-e mədə o-ra-e-o] sehr-rə
he-ERG *wine* *3S–3P-give*-NMLZ *elder*-PL
'the elders to whom he gave wine'
(Watters, 2002: 201–206)

There is a clear correlation between the pervasiveness of action nominals in complementation and the extent to which they show sentential/verbal properties. Thus, in most of the languages with the sentential ANC type, ANs are among the predominant forms used in complementation; these are also inflectional according to most criteria and often retain, at least partly, such verbal categories as tense/aspect, voice, etc. The same tendencies seem to be operative for other nominalizations as well; thus, in languages where argument nominalizations constitute the main relativization strategy, they tend to behave like inflectional forms and retain a good portion of sentential/verbal properties. However, no systematic research has yet been conducted on argument nominalizations.

Nominalizations are also frequently used in analytical (periphrastic) verb forms, with an impressive diversity of resulting grammatical meanings. Thus, progressives often grammaticalize from locational constructions with verbal nouns, 'X is located in V-ing.' The English continuous forms (*Peter is going*) exemplify this development. In Iraqw, the future is expressed by the auxiliary *aw* 'to go' with the verbal noun of the main verb as the object preceding it (the complement of the verbal noun forms a genitive construction with the verbal noun), as in ex. (11):

(11)

makay	i	ma'á
animals	SUBJ.*3*	*water*.CONSTR
wahúngw	ay-á'	
drinking.CONSTR	*go:3*-PL	

'The animals will drink water.' (Mous, 1983: 267)

Finally, (erstwhile) nominalizations may also develop main-clause (or independent-clause) functions. Thus, in a number of languages nominalizations as independent clauses are used for various discourse-pragmatic functions, primarily in backgrounded portions of discourse, e.g., setting the scene, or providing parenthetical, subsidiary information. Variations on the theme are attested in languages as diverse as Japanese (Iwasaki, 2000), Navajo (Mithun, 2002), and Kham (Watters, 2002). Mithun suggested that these functions arise due to extension from marking syntactic relations among sentences to marking pragmatic relationships among sentences in discourse.

This is not the only scenario by which nominalizations can acquire main-clause functions. Gildea (1998) suggested that the verb forms of main clauses in many Cariban languages descend from earlier copular sentences based on nominalizations, from which the copula has gradually disappeared, and showed which nominalizations become which tenses and aspects. Thus, e.g., agent nominalizers become immediate future, habitual, and 'universal' tense-aspects, object nominalizers become past, perfect, and perfective, and action nominalizers become 'universal,' immediate future, and imperfective tense-aspects.

Introduction

All primates live in social groups. Some, like orangutans, live a largely solitary life, but come together for mating, aggressive competition, and offspring care. Others, such as chimpanzees, live in large communities, but on a day-to-day basis exist in small ephemeral parties. Independent of group size and composition, monkeys and apes engage in a wide variety of social and nonsocial activities including the discovery of food, the detection of predators, intergroup encounters, group movement, play, grooming, aggressive attacks, coalitions, submissive retreats, and reconciliatory actions designed to redress imbalances in a relationship. In principle, one can readily imagine the adaptive significance of a signaling system capable of informing others of these various activities. Of particular use would be a vocal system designed to convey such information in the absence of any other contextual information. Such a system would enable Monkey A to inform Monkey B of the location, movement, and type of predator, and monkey B would be able to decode this information and more, including the fact that monkey A is a member of the same species, same group, is high ranking, and male. This hypothesis about adaptive design is only partly accurate. Nonhuman primates do produce vocalizations in a variety of contexts, and listeners do extract considerable information from the signal. But there are significant constraints on the kind of information conveyed and the kind of information extracted. These constraints are both internal (peripheral and central processing mechanisms) and external (habitat, climate, distance to receivers, competing acoustic signals) to the animals themselves.

Students of animal behavior have long argued over the proper definition of communication (Hauser, 1996; Bradbury and Vehrencamp, 1998; Owings and Morton, 1998). Early theories, centered primarily in classical ethology, focused on the veridical transmission of information from sender to receiver. One variant of this view borrowed from engineering, and in particular Shannon-Weaver information theory. Communication was said to occur if a receiver's uncertainty about an event was reduced by the information transmitted in the sender's signal. Critics of this information perspective emerged with the sociobiology revolution. Dawkins and Krebs (1978) argued that a veridical signaling system was invadable by a mutant who generated the same signal but with a different, and deceptive motivation. Thus, for example, if an aggressive signal was designed to convey information about the probability of escalating aggression, then a mutant who always signaled the highest level of aggressive intent, but was bluffing, would always win because receivers would readily back down. Thus, so Dawkins and Krebs originally argued, the adaptive function of communication is for signalers to manipulate the behavior of receivers. This view was quickly criticized for being signaler-centric. Dawkins and Krebs responded by modifying their original model to include both manipulative signalers and skeptical receivers. Thus, communication evolves as an arms race in which selection favors signals designed to manipulate the behavior of receivers for fitness gains, and counterselection favors receivers that distinguish between truths and lies. Riding along with this selfish-gene perspective was

Introduction

All primates live in social groups. Some, like orangutans, live a largely solitary life, but come together for mating, aggressive competition, and offspring care. Others, such as chimpanzees, live in large communities, but on a day-to-day basis exist in small ephemeral parties. Independent of group size and composition, monkeys and apes engage in a wide variety of social and nonsocial activities including the discovery of food, the detection of predators, intergroup encounters, group movement, play, grooming, aggressive attacks, coalitions, submissive retreats, and reconciliatory actions designed to redress imbalances in a relationship. In principle, one can readily imagine the adaptive significance of a signaling system capable of informing others of these various activities. Of particular use would be a vocal system designed to convey such information in the absence of any other contextual information. Such a system would enable Monkey A to inform Monkey B of the location, movement, and type of predator, and monkey B would be able to decode this information and more, including the fact that monkey A is a member of the same species, same group, is high ranking, and male. This hypothesis about adaptive design is only partly accurate. Nonhuman primates do produce vocalizations in a variety of contexts, and listeners do extract considerable information from the signal. But there are significant constraints on the kind of information conveyed and the kind of information extracted. These constraints are both internal (peripheral and central processing mechanisms) and external (habitat, climate, distance to receivers, competing acoustic signals) to the animals themselves.

Students of animal behavior have long argued over the proper definition of communication (Hauser, 1996; Bradbury and Vehrencamp, 1998; Owings and Morton, 1998). Early theories, centered primarily in classical ethology, focused on the veridical transmission of information from sender to receiver. One variant of this view borrowed from engineering, and in particular Shannon-Weaver information theory. Communication was said to occur if a receiver's uncertainty about an event was reduced by the information transmitted in the sender's signal. Critics of this information perspective emerged with the sociobiology revolution. Dawkins and Krebs (1978) argued that a veridical signaling system was invadable by a mutant who generated the same signal but with a different, and deceptive motivation. Thus, for example, if an aggressive signal was designed to convey information about the probability of escalating aggression, then a mutant who always signaled the highest level of aggressive intent, but was bluffing, would always win because receivers would readily back down. Thus, so Dawkins and Krebs originally argued, the adaptive function of communication is for signalers to manipulate the behavior of receivers. This view was quickly criticized for being signaler-centric. Dawkins and Krebs responded by modifying their original model to include both manipulative signalers and skeptical receivers. Thus, communication evolves as an arms race in which selection favors signals designed to manipulate the behavior of receivers for fitness gains, and counterselection favors receivers that distinguish between truths and lies. Riding along with this selfish-gene perspective was

Figure 1 The basic structure of communication systems. Shown are the four central elements that comprise communication: the sender emits a signal that travels through a medium to a receiver. Shown is a vocal communication in which the signal is a vocalization and the medium is a forested environment.

Zahavi's (Zahavi, 1975) handicap principle, often interpreted as a specific explanation for mating behavior, but originally proposed as a general theory of signaling. For Zahavi, signals provide veridical information about the signaler if, and only if, there are costs to signaling relative to current condition, and the capacity to generate such cost-bearing signals is heritable. Although there have been several empirical examples supporting Zahavi's intuition (e.g., stotting in gazelles, courtship displays in several bird species), it is also clear that honesty can emerge in the absence of significant costs. For example, a series of studies by Fitch and colleagues indicate that physical constraints anchor honesty in the absence of costs (e.g., the length of the vocal tract correlates with body size which provides, via formant frequency dispersion, an honest indicator of size (Fitch, 1997)).

All of these definitions of communication have pros and cons, and most side step the cognitive mechanisms underlying both the production and perception of communicative signals. For purposes of exposition, we borrow from these different definitions and focus on what we see as the most empirically tractable aspects: the information encoded in the signal, the transmission medium, and the perceptual decoding of and response to the signal (Figure 1).

In the present article, we focus our discussion on communication in nonhuman primates (see chapters of this volume for similar discussions of other taxonomic groups). We focus on vocal communication because there has been considerably more progress for this sensory channel in primates than for all others. This is largely because the analytical techniques for analyzing the signal and testing its perceptual significance in primates are far more sophisticated than for the visual, tactile or olfactory channels. We begin with a discussion of call context, focusing on three functional problems: food, sex, and antipredator alarm. We then focus on the potential for signalers to convey information about individual, sex, and group identity, and the capacity for receivers to decode this information. We end this article with a discussion of some pressing gaps in our understanding and the need to develop new analytic tools and comparative data sets.

Call Context

Primates produce an astonishing array of vocalizations – from the simple, tonal phees of the common marmoset (Figure 2B), to the spectrotemporally complex syllable sequences of the chimpanzee pant hoot (Figure 2A), to the moving formants found in rhesus monkey girneys (Figure 2C). There is enormous variability in the spectrotemporal structure of different call types within species and in the acoustic properties of particular calls within and between individuals. These observations raise two questions: to what extent is the variability in signal morphology behaviorally relevant and how shall we go about quantifying call morphology? One method is to chart the association between social and ecological situations and call morphology. More recent work has extended these earlier findings to explore the possibility that, like human words, primate vocalizations have the capacity to pick out salient objects and events in the environment, and convey this information to listeners. We focus here on functional aspects of these calls, leaving aside discussion of their cognitive substrates.

Figure 2 Spectrograms show inter-species variation in the acoustic structure of primate vocalizations. For each spectrogram, the X-axis shows time and the Y-axis shows frequency. Depicted are (a) chimpanzee pant hoot, (b) common marmoset phee, and (c) rhesus monkey girney.

Food

Many primates produce distinct calls when discovering or eating food. Call rate appears to correlate with hunger in rhesus macaques (*Macaca mulatta*), with food preference in cotton-top tamarins (*Saguinus oedipus)*, with amount of food and location in toque macaques (*M. sinica*), and with amount of food and whether that food is divisible in chimpanzees (*Pan troglodytes*). In addition, distinct vocalizations for low quality/common and high quality/rare foods have been observed in rhesus macaques (Hauser, 1996).

Rhesus macaques not only produce acoustically distinct vocalizations for low and high quality food items, they also appear to recognize these categories. In a habituation–discrimination experiment (Hauser, 1996), habituation was shown to transfer between two high quality food call types ('warbles' and 'harmonic arches') despite the fact that they are acoustically distinctive; this suggests that both calls are classified as falling within the same functional category. Information in rhesus food calls was shown to be relevant to conspecifics in another context as well (Hauser, 1996). Experimenters observed individual rhesus following discovery of food. Discoverers produced food calls 45% of the time. However, because of the density of the population, other conspecifics detected the food discovery 90% of the time. On average, vocal discoverers consumed more food than silent discoverers because silent discoverers, when detected, were often chased away from the food or aggressively attacked. Similar results have also been observed in white-faced capuchins (*Cebus capucinus*) (Gros-Louis, 2004).

Predators

Many primates produce alarm calls in response to predators. Several species, including Barbary macaques (*M. sylvanus*), chacma baboons (*Papio hamadryas*), ring-tailed lemurs (*Lemur catta*), redfronted lemurs (*Eulemur fulvus rufus*), Verraux's sifakas (*Propithecus verreauxi verreauxi*), Diana monkeys (*Cercopithecus diana*), and most famously, vervet monkeys (*C. aethiops*) (Cheney and Seyfarth, 1990), produce acoustically distinctive alarm calls to different predators. Vervets living in Amboseli National Park, Kenya, produce acoustically distinctive alarm calls to large felines (leopards, etc.; Figure 3A), large

Figure 3 Spectrograms of the three major vervet monkey alarm vocalizations. For each spectrogram, the X-axis shows time and the Y-axis shows frequency. Shown are the species-typical alarm calls produced in response to (A) leopards, (B) eagles, and (C) snakes.

Control	*Leopard alarm call*	*Eagle shriek*
	Eagle alarm call	*Leopard growl*

Figure 4 Outline of the experimental design used in Zuberbuhler *et al.* (1999). This experiment consists of two trials (prime/probe) for each of the three test conditions (baseline/test/control). For these experiments, the prime stimulus was presented first, followed by the probe stimulus. The logic here is that if the information provided to the subjects is similar in both the prime and probe trials, then subjects should show a response to the prime stimulus, but not the probe stimulus. If, however, the information is different, subjects should show similar levels of response in both trials.

raptors (martial eagles and crowned eagles; Figure 3B), snakes (pythons and mambas; Figure 3C), baboons, and some humans (e.g., the Maasai who occasionally hunt or threaten them). What information is transmitted in these signals? Two criteria must be met for an alarm vocalization to transmit information about a specific predator as opposed to predators or fearful stimuli more generally: (1) the vocalization must be evoked by the presence of the specific predator, and not by any other stimuli and (2) playback of the vocalization alone must be sufficient to produce the same response as the presence of the predator. If these two criteria are met, the alarm call is considered 'functionally referential' (Marler *et al.*, 1992), that is, it functions as if it conveys information regarding a specific predator. Studies on vervet monkeys, ring-tailed lemurs, and Diana monkeys provide evidence for functionally referential alarm calls. We focus here on the Diana monkey as this work has included some of the most detailed perceptual experiments to date.

Diana monkeys live in small single male, multi-female groups. Female Diana monkeys produce eagle alarm calls in response to playbacks of both crowned eagle shrieks and male Diana monkey eagle alarm calls and produce leopard alarm calls to playbacks of both leopard growls and male leopard alarm calls (Zuberbuhler *et al.*, 1997). Because male alarm calls and the calls of the predator that elicits them are acoustically distinct, the commonality in the females' response suggests that what is driving the response is the commonality of referent. Further evidence for this comes from an elegant priming study in which responses to the acoustic and referential features of the calls were assessed (Zuberbuhler *et al.*, 1999). In the study, a priming stimulus was presented, followed five minutes later by a probe stimulus (see Figure 4). The prime-probe pairs fell into three categories: the baseline condition, in which the prime and the probe were identical (e.g., both leopard growls), a test condition, in which the prime and the probe differed in acoustic structure but had identical referents (e.g., a male leopard alarm call followed by a leopard growl), and a control condition in which the prime and the probe differed in both acoustic structure and referent (e.g., a male leopard alarm call followed by an eagle shriek). In the baseline condition females produced significantly fewer alarm calls to the probe than to the prime while in the control condition females responded strongly to both the probe and the prime. Habituation therefore occurs when prime and probe share both referential and acoustic features, and does not occur when they share neither referential nor acoustic features. The response of females to the test condition, in which prime and probe share referential but not acoustic features, was similar to that in the baseline condition: females produced significantly fewer alarm calls to the probe than to the prime, suggesting that they were attending to the referential features of the probe.

Mating

A wide variety of primates produce vocalizations in the context of mating. These vocalizations are

typically referred to as copulation calls, and are produced immediately before, during or following copulation. In some species it is the male who produces copulation calls, in other species the female emits the vocalizations, and in a handful of species both sexes produce copulation calls (Hauser, 1996). Because of the variability in the vocal behavior surrounding copulation calls, the functional significance of this class of vocalizations has been difficult to ascertain. However, some similarities exist between species that suggest these calls are likely to play a role in mating behavior. For example, copulation calls are acoustically distinctive within the repertoire, carry information about individual identity, and are often produced at high intensities. These properties enable group members to identify and localize the caller, as well as the context. Although copulation calls have been investigated in a wide range of species, including Old World monkeys and apes, the most detailed work concerning the function of these calls comes from studies of Barbary macaques.

Barbary macaques live in social groups consisting of multiple males and females. Their mating system is typically classified as polygynous, with both males and females mating with multiple individuals. During copulation, females produce acoustically distinct copulation calls. Because these calls can be heard from several meters away, it was proposed that they could function to incite competition between males (Hamilton and Arrowood, 1978). Such competition could occur either through direct male–male competition, with the winner of a fight gaining access to a female, or through sperm competition from mating with multiple males in a short period of time. To address this issue, Semple (1998) conducted a series of field playback experiments. Results indicated that males were more likely to approach females following the playback of her copulation call relative to controls suggesting that copulation calls functioned to alert males that she was currently in estrous. Furthermore, when two males were in the vicinity of the playback, only the more dominant male approached. These data provided evidence for both types of competition because although males were drawn to females after hearing her copulation calls (potentially leading to increased sperm competition), dominant males gained greater access to these females than lower ranking males (consistent with male–male competition). Further experiments showed that the Barbary macaque copulation calling system consisted of another layer of complexity. Analyses showed that copulation calls produced during peak estrous were acoustically distinct from those calls produced early in the estrous cycle (Semple and McComb, 2000). Following this analysis, Semple and McComb conducted a playback experiment in which peak estrous and early estrous copulation calls were broadcast to males. Results revealed that male subjects were more likely to approach females following playback of calls produced during peak estrous than those produced early in the estrous cycle, thus confirming that the acoustic differences between calls produced at these two periods of estrous were both perceptible and meaningful to male macaques. Overall, these data provide evidence that the Barbary macaque copulation call is a salient acoustic cue that plays a significant role in modulating male mating behavior.

Caller Identity

In this section, we focus on three layers or levels of identity: individual, sex, and group. Major research questions in this area are: (1) What are the necessary and sufficient acoustic features associated with an individual's acoustic signature? and (2) To what extent do listeners recognize specific individuals, their sex, or their group identity based on particular features of the signal?

Individual

It has long been known that individual identification based on an acoustic signal is technically possible – in the same way that genetics and environment combine to produce individually distinctive faces, all individuals have individually distinctive voices. However, whether a conspecific can identify an individual based purely on a vocal signal depends on several factors. One important factor is purely perceptual: the listener's auditory system simply may not be sensitive enough to detect the individual distinctiveness in a vocalization. Another factor is the specific vocal signal involved: just as some vocalizations appear to be designed to be either difficult or easy to localize (Marler, 1955), vocalizations appear to vary in their degree of individual distinctiveness. One candidate for the acoustic basis of individual recognition in primate vocal signals is the spectral patterning introduced by vocal tract filtering. The spectral peaks introduced by the vocal tract have been shown to be individually distinctive across two very different calls (coos and grunts) in the rhesus macaque (Rendall *et al.*, 1998). The vocal tract filtering hypothesis is supported by the observation that screams, calls that do not display prominent vocal tract filtering peaks, are also less individually distinctive in playback experiments. However, other experiments in rhesus and pigtail macaques (Gouzoules *et al.*, 1984; Gouzoules and Gouzoules, 1990) have found individual recognition with screams, raising the possibility of a different, or at least an additional, acoustic substrate for

individual recognition. Another candidate for individual recognition is the degree of acoustic variability within and between calls (Fitch *et al.*, 2002).

Regardless of the specific substrate, there are many *a priori* reasons for thinking that primates would benefit from the ability to recognize the identity of a vocalizer: (1) many primates live in dense cover and are often out of sight of group members, (2) success in the social domain often depends on support from conspecifics (particularly kin), and (3) an acoustic signal is better suited to eliciting support from social partners than a visual signal because acoustic signals can travel in 360 degrees and over large distances. Individual recognition by voice has been elegantly demonstrated in vervet monkeys.

Vervet monkey females remain in their natal troupe whereas males emigrate. Each troupe, therefore, consists of several groups of closely-related females. Alliances between close kin during agonistic encounters are common and have repercussions in terms of maintenance of dominance rank, access to scarce resources and reproductive success. When a juvenile vervet vocalizes during an agonistic encounter, its mother often intervenes to support her offspring. Cheney and Seyfarth (1980) took advantage of this behavior to test whether or not vervet females could recognize the vocalization of an individual juvenile. They began by locating three females whose juvenile offspring were out of sight. They then recorded the behavior of the three females before and after playback of the recruitment scream of the juvenile offspring of one of the females. They showed that although all three females responded to the playback by looking in the direction of the concealed playback speaker, the mother of the juvenile whose call had been played responded with a significantly shorter latency and longer duration (Figure 5) than did the other two, 'control,' females. Interestingly, the control females also were more likely to look at the mother after playback. These two pieces of data together suggest that vervet females are able to recognize the individual who produced a particular vocalization.

Similar abilities have been shown using a variety of methodologies in yellow baboons (*P. cynocephalus*), rhesus macaques, Barbary macaques (where it has been shown to emerge as early as 10 weeks of age), pygmy marmosets (*Cebuella pygmaea*), chimpanzees, grey-cheeked mangabeys (*Cercocebus albigena*), squirrel monkeys (*Saimiri sciureus*) and cotton-top tamarins (Snowdon, 1986).

Figure 5 Bar graph showing results from individual recognition playback experiments in vervet monkeys. In each playback, juvenile screams were played back to the juvenile's mother and two control females who also had offspring. Results show that mothers responded with a faster latency and with longer looks than control females. The Y-axis plots responses in frames [18 frames/second]. Redrawn from Cheney and Seyfarth (1980).

Sex

As with many aspects of primate behavior, sex differences exist in primate vocal behavior. Sex differences emerge both in the overt behavior associated with vocalizations, as well as the acoustic structure of the vocalizations themselves. Producing vocalizations with sex differences may be crucial for animals such as primates that must navigate complex social systems. Being able to determine an individual's sex without having experience with that individual is likely to provide one with cues about how and whether to interact with an animal before coming into physical or visual contact with the individual. Although the acoustic differences between male and female primates are often reported, little is known about the perceptual salience and behavioral relevance of this information.

Recently, researchers have begun to address this issue using different experimental techniques. In a study of wild baboons, Rendall and colleagues (Rendall *et al.*, 2004) recorded grunts, a close distance affiliative call. Acoustic analyses showed that the fundamental frequency and the first three formant frequencies were lower in males than females suggesting that these acoustic differences could potentially be used to determine the sex of a caller. To test this possibility, Rendall and colleagues trained captive baboons to discriminate between exemplars of male and female grunts in a psychophysical experiment. Results indicated that subjects successfully discriminated between grunts produced by males and females suggesting that this could be accomplished using the natural acoustic differences present in the vocalizations. Although these data show that the animals are able to perceive a difference between male and female

calls following training, they do not address whether the animals are able to do this naturally. Evidence of spontaneous discrimination is critical for making arguments about whether information about the caller's sex is used in natural behavioral interactions. This gap in our understanding was recently addressed in a study of captive cotton-top tamarins.

Cotton-top tamarins produce a species-specific vocalization called a combination long call (CLC) when separated from group members. This long distance, multisyllabic vocalization typically elicits antiphonal calls and approach behavior from conspecifics. Acoustic analyses of CLCs showed that male calls consisted of significantly shorter syllables than female calls. To test the perceptual and behavioral salience of these acoustic differences, Miller and colleagues (Miller *et al.*, 2004) conducted a phonotaxis experiment. In phonotaxis experiments, subjects are presented with vocalizations from two speakers situated equidistant from subjects and scored for which speaker is approached first. In the first experiment, subjects were presented with naturally produced exemplars of male and female CLCs. Subjects showed significant preference to approach female CLCs suggesting that they could discriminate between the sexes of the caller. When the syllable durations were then manipulated to be identical, subjects no longer showed this behavioral bias, suggesting that syllable duration is a critical feature in sex recognition. Building on this result, a second experiment tested whether the basis for sex differences in CLCs was due to perceptual biases in signal receivers. In this experiment, subjects were first presented with CLCs from animals of the opposite sex in which the syllable durations were manipulated to be at the high and low end of the naturally produced range. Results showed that whereas males showed a preference for female calls with the longest syllable durations, females preferred male calls with the shortest syllable durations. When the syllable durations were manipulated to be outside the naturally produced range, this preference persisted suggesting that sensory biases may impose selective pressure on the structure of CLCs.

Group Membership

Similarities in the spectrotemporal properties of vocalizations within primate social groups have been shown in a variety of species: chimpanzees, Barbary macaques, pigtail macaques (*M. nemestrina*), rhesus macaques, cotton-top tamarins, and mouse lemurs (*Microcebus murinus*). These acoustic similarities are called different things by different authors: dialects, vocal signatures or vocal accommodation (Fischer, 2002). However, they all may serve the purpose of signaling current group membership. This may be particularly useful in species in which group membership is relatively fluid, or in species, such as most of the Old World monkeys, in which there are many different kin groups within a single troupe.

A group level signature has been shown in the chimpanzee's pant hoot. This vocalization, which consists of a an introductory phase of long tonal syllables, a buildup phase with shorter elements, a loud and high frequency climax phase and a short let down phase (see **Figure 2A**), is a long-distance vocalization used by males to maintain contact between allies. Mitani and Gros-Louis (1998) recorded pant hoot choruses between a variety of males in Mahale Mountains National Park in Tanzania. They observed that the pant hoots of males that chorus together are more similar to each other than when they are chorusing with other males, providing a potential cue for current alliance membership. Variation in pant hoot structure also was shown by Marshall and colleagues (Marshall *et al.*, 1999), who described the introduction of a spectrally distinct pant hoot syllable (the 'Bronx cheer' or 'raspberry' variant) by a single individual into a captive colony of chimpanzees. Finally, Crockford and colleagues (Crockford *et al.*, 2004), have observed variation in pant hoot structure between neighboring chimpanzee communities, but not between isolated communities. These authors suggest that groups that are within acoustic contact actively modify their vocalizations to make them distinctive, allowing community allegiance to be detectable at a distance.

However, all studies on group-specific signatures to date have been observational. It is still an open question whether these signatures are meaningful to receivers, though it seems likely, given that the tendency to produce such signatures appears to be widespread among primates. Demonstrating the salience of such signatures, however, will be challenging, as any discrimination based on a group-specific signature might also be supported by individual recognition. It will, therefore, be necessary to create synthetic calls in which a signature at the individual level is maintained, while the group level signature is manipulated.

Future Directions

Primate senders can clearly transmit a variety of information to primate receivers. This information can range, as we have discussed, from information about the sender's location, size, or sex, to information about an external object, such as quality of food or predator type. In addition, other experiments

have shown that signalers can convey information about dominance rank, degree of risk in an agonistic encounter, call bout termination and contact with another conspecific group. Given the richness of information transfer, what are the next steps in the study of primate vocal communication?

Initially primate vocal repertoires were characterized as either 'discrete' or 'graded.' Discrete vocal repertoires contain calls whose spectrotemporal features are distinct from one another, whereas graded systems are those in which there are intermediate forms between many of the calls types. One problem with this sort of distinction is that a sparsely sampled (either in terms of total number of calls recorded, or type and complexity of social contexts observed) graded system will look like a discrete system. More critically, describing a system as graded or discrete assumes that the experimenters estimation of the relevant acoustic parameters matches those of the species under study. Selection of appropriate acoustic features is implicit in identifying call types and critical to asking experimentally rigorous questions. This task is complicated by the fact that primate vocalizations are extremely variable, both within and between individuals. How do we determine what variation is meaningful? Historically vocalizations have been analyzed based on features that are obvious in a spectrogram. Unfortunately, there is no guarantee that the acoustic features that are obvious to a human observer in a spectrogram are features that are behaviorally meaningful to a nonhuman primate (Owren and Linker, 1995). We are therefore faced with a threefold problem: (1) what features exist in the vocalizations? (2) Of these features, which features are behaviorally relevant? and (3) Are these features perceived as discrete or graded? Addressing question 1 requires analysis techniques suitable to the high-dimensional and variable nature of primate vocalizations. Addressing questions 2 and 3 requires behavioral experiments in which identified features are tested for behavioral relevance.

Mathematical methods designed to uncover the low-dimensional structure embedded in high dimensional data have been developed in a variety of fields and some, such as multidimensional scaling (MDS) and principle components analysis (PCA), have been adopted by bioacousticians. However, there are two drawbacks to these methods, one in implementation and one inherent to the analytic techniques themselves. The implementation problem is that researchers usually carry out the feature extraction by hand, and then use these handpicked features in the analysis (thus exposing the results to bias). This problem can be mitigated, however, by selecting a large number of uncorrelated features for analysis. The second problem is more critical, namely that both MDS and PCA require a large number of high quality recordings to be effective. Until recently such data sets have been rare in the primate literature, because of the difficulty of recording vocalizations in normal social contexts.

In the past there has often been a tradeoff between the quality of the recording and the naturalness of the social situation – it is no accident that some of the best studied vocalizations are either very loud, common vocalizations (like alarm calls) or calls that can be elicited by isolation (e.g., the CLC of the cotton-top tamarin or the isolation peep of the squirrel monkey). The short range vocalizations of primates living in large social networks, with the most potential for information transmission of a high degree of complexity, are often the most difficult to record and then test experimentally. To extend our investigations to the rest of repertoire, we need a method for collecting large, high quality data sets, particularly of rare and quiet vocalizations. Advances in radiofrequency transmitters, making them both smaller and more affordable, now allow the possibility of recording large numbers of calls from freely behaving animals, both in captive colonies and in the wild. The advantages of such systems are (1) high-quality recordings of clearly identified callers are possible because the microphone is attached to the animal, (2) recordings can occur during all social contexts, (3) a large number of recordings can be collected automatically, and (4) if all members of a social group carry transmitters, information about call sequencing and bout structure can also be collected. Such systems, in conjunction with observations of behavioral context, will allow a deeper look into nonhuman primate vocal behavior.

Finally, researchers must begin to recognize the limitations of current perceptual tests. Most playbacks elicit a simple orienting response associated with a particular reaction time and duration – the robust behavioral responses elicited by alarm calls, or the antiphonal calling to contact calls, are relatively rare. Following the lead of researchers working on other non-primate systems, including frogs, birds, and humans, single playback experiments must be extended to include habituation–dishabituation procedures, phonotaxis, interactive playbacks, and physiological measures (e.g., heart rate, skin conductance, neural recordings) to complement orienting responses.

Natural vocal communication offers a privileged window into primate mental processes, but studies of primate vocal communication to date have focused on the transmission of relatively simple types of information. However, primates produce a richness of vocalization in a diversity of contexts. This variation

suggests that a considerable amount of information is potentially encoded and decoded about the signaler's motivational and affective state and the nature of the social and ecological environment. As the field of primate vocal communication advances to include more complex types of information transmission, the study of primate vocal communication has the potential to offer insight into the cognitive substrates underlying the primate mind.

Nonmanual Structures in Sign Language

O A Crasborn, Radboud University Nijmegen, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

General Characterization

Sign languages are often characterized as manual–visual languages, with the perceptual channel being vision and the articulatory mechanism the hands. It has long been recognized that besides the hands, non-manual articulations play an important role in all sign languages studied to date. Non-manual features in sign languages do not only include facial actions and expressions but also movements and positions of the head, shoulders, and upper body as a whole. Although the area of the body below the waist (hips, legs, and feet) is occasionally used as the location for manual articulations in some sign languages, it very rarely serves as an active articulator.

Aspects of facial expression that appear to be relevant include the eyebrows, eyelids, eye gaze, cheeks, nose, lips, and jaw. Together with the use of the head, shoulders, and body, this list constitutes a large number of potentially independent articulators that can be used simultaneously with the manual components and with each other. This simultaneity is a striking feature of all sign languages.

The different non-manual articulators play a role at all levels of linguistic structure, from meaningless phonological components of lexical items to discourse markers. Their role is often compared to that of prosody, particularly pitch or intonation in spoken languages, both in the sense of being superimposed on 'segmental' (manual) material and in the sense of the multiple functions that non-manual signals fulfill. Non-manual features also resemble intonation in often taking on paralinguistic roles.

Facial expressions in particular, but also head and upper body movements, also figure prominently in nonverbal communication among hearing people using spoken languages. Facial expressions revealing emotional states have been studied in great detail from a psychological point of view, and to a great extent they have universal forms among all human cultures (Ekman, 1982). Although such expressions can also be found universally in communication between Deaf people, non-manual expressions also have a range of more narrow linguistic functions in sign languages. Not only is the functioning limited to expressing particular linguistic features but also the form is very specific, typically consisting of a narrow subset of the facial musculature (e.g., affecting only the eyebrows or cheeks). Emotional facial expressions, in contrast, are typically marked by the involvement of larger facial areas. Baker-Shenk (1983) was one of the few authors to systematically investigate this distinction, and she found a difference in timing as well: in her data set, grammatical facial expressions showed clear and rapid onsets and offsets, whereas emotional facial expressions were characterized by a more gradual and more variable pattern over time.

It is a commonly accepted intuition that linguistic non-manual signals have grammaticalized from emotional facial expressions, but few studies have explicitly addressed this hypothesis. Similarly, little is known about how linguistic and emotional facial expressions can occur simultaneously in sign language utterances.

A broad distinction in linguistic facial markers can be made between the lower and upper half of the face. Actions of the mouth, jaw, cheeks, and nose are typically specified in the lexicon, whereas actions of the eyebrows and eyelids as well as eye gaze typically have a function at a syntactic or discourse level.

Phonological and Lexical Roles

The phonological shape of a free morpheme in sign languages is typically composed of aspects characterizing the hands (*see* **Sign Language: Phonology**). In some signs, however, there is also a phonological role for non-manual aspects, in the sense that they are obligatory formal features that do not carry meaning themselves. **Figure 1** illustrates this for the sign TRY-OUT in NGT (Nederlandse Gebarentaal, Sign Language of the Netherlands; Ethnologue name, Dutch Sign Language). The round cheek that is contacted by the index finger contrasts this sign with the sign DAYS, which has a flat cheek.

Forward and backward leans of the head and/or body have also been found to serve a phonological

General Characterization

Sign languages are often characterized as manual–visual languages, with the perceptual channel being vision and the articulatory mechanism the hands. It has long been recognized that besides the hands, non-manual articulations play an important role in all sign languages studied to date. Non-manual features in sign languages do not only include facial actions and expressions but also movements and positions of the head, shoulders, and upper body as a whole. Although the area of the body below the waist (hips, legs, and feet) is occasionally used as the location for manual articulations in some sign languages, it very rarely serves as an active articulator.

Aspects of facial expression that appear to be relevant include the eyebrows, eyelids, eye gaze, cheeks, nose, lips, and jaw. Together with the use of the head, shoulders, and body, this list constitutes a large number of potentially independent articulators that can be used simultaneously with the manual components and with each other. This simultaneity is a striking feature of all sign languages.

The different non-manual articulators play a role at all levels of linguistic structure, from meaningless phonological components of lexical items to discourse markers. Their role is often compared to that of prosody, particularly pitch or intonation in spoken languages, both in the sense of being superimposed on 'segmental' (manual) material and in the sense of the multiple functions that non-manual signals fulfill. Non-manual features also resemble intonation in often taking on paralinguistic roles.

Facial expressions in particular, but also head and upper body movements, also figure prominently in nonverbal communication among hearing people using spoken languages. Facial expressions revealing emotional states have been studied in great detail from a psychological point of view, and to a great extent they have universal forms among all human cultures (Ekman, 1982). Although such expressions can also be found universally in communication between Deaf people, non-manual expressions also have a range of more narrow linguistic functions in sign languages. Not only is the functioning limited to expressing particular linguistic features but also the form is very specific, typically consisting of a narrow subset of the facial musculature (e.g., affecting only the eyebrows or cheeks). Emotional facial expressions, in contrast, are typically marked by the involvement of larger facial areas. Baker-Shenk (1983) was one of the few authors to systematically investigate this distinction, and she found a difference in timing as well: in her data set, grammatical facial expressions showed clear and rapid onsets and offsets, whereas emotional facial expressions were characterized by a more gradual and more variable pattern over time.

It is a commonly accepted intuition that linguistic non-manual signals have grammaticalized from emotional facial expressions, but few studies have explicitly addressed this hypothesis. Similarly, little is known about how linguistic and emotional facial expressions can occur simultaneously in sign language utterances.

A broad distinction in linguistic facial markers can be made between the lower and upper half of the face. Actions of the mouth, jaw, cheeks, and nose are typically specified in the lexicon, whereas actions of the eyebrows and eyelids as well as eye gaze typically have a function at a syntactic or discourse level.

Phonological and Lexical Roles

The phonological shape of a free morpheme in sign languages is typically composed of aspects characterizing the hands (*see* **Sign Language: Phonology**). In some signs, however, there is also a phonological role for non-manual aspects, in the sense that they are obligatory formal features that do not carry meaning themselves. Figure 1 illustrates this for the sign TRY-OUT in NGT (Nederlandse Gebarentaal, Sign Language of the Netherlands; Ethnologue name, Dutch Sign Language). The round cheek that is contacted by the index finger contrasts this sign with the sign DAYS, which has a flat cheek.

Forward and backward leans of the head and/or body have also been found to serve a phonological

Figure 1 Obligatory non-manual component in the NGT sign TRY-OUT: cheek blown on one side.

Figure 2 Mouth gesture in the NGT sign TO-BE-PRESENT.

role in American Sign Language (ASL) (Wilbur and Patschke, 1998).

The most common non-manual articulator in lexical items is the mouth. One finds both articulations that are borrowed from, or can be traced back to, spoken words (termed 'mouthings' or 'spoken components') and forms that have no apparent relation to the surrounding spoken language (termed 'mouth gestures' or 'oral components'). Examples are presented in Figures 2 and 3. In the NGT sign BE-PRESENT (Figure 2), the rounded and pursed lips, typically accompanied by egressive airstream and resembling IPA [ʃ], bear no relationship to any Dutch word that is semantically close. (The Dutch gloss is 'aanwezig,' IPA (a:nwe:zəχ).) In contrast, the sign TREE (Figure 3) is in most realizations accompanied by the silent articulation of the Dutch word [bo:m] 'tree.'

There are signs that differ only in the form of their mouthing. For example, the NGT minimal pair BROTHER and SISTER is only differentiated by the (silent) articulation of the Dutch words 'broer' versus 'zus' (Schermer, 1990).

There has been a vivid debate in the literature on the status of mouth actions that are derived from spoken words. Because sign languages are always surrounded by spoken languages, and since many Deaf sign language users are also competent in a spoken language to a certain degree, some researchers argue that mouthings are an instance of code mixing rather than parts of the sign language lexicon itself. It does appear that, at least in some Deaf cultures, mouthings are used in any sign language interaction, irrespective of the context (e.g., the presence versus the absence of hearing people) or the embedding of the signer in the Deaf community (Ebbinghaus and Heßmann, 2001). Mouthings do not figure equally prominently in all sign languages: Western European sign languages seem to show a larger frequency of mouthings both in the lexicon and in actual discourse than ASL or Adamrobe Sign Language (a village-based sign language in Ghana).

In addition to this phonological role for actions of the face in signs that also have a manual component, there are free morphemes that consist only of a non-manual specification. These typically function as adverbs that are realized simultaneously with action verbs produced on the hands. In NGT, for example, the form 'pursed lips' functions as an adverb with the meaning 'in a relaxed manner'; blown cheeks and squinted eyes function as an adverb with the meaning 'with difficulty.'

Syntactic and Discourse Roles

The role of non-manual expressions in marking various sentence types, for example, distinguishing statements from questions, has been clear since the studies of ASL in the 1970s. These markings typically concern features of the eyebrows and head. An example from NGT is given here. The syntactic category 'yes–no question' is marked in this language by a slight forward tilt of the head and raising of the eyebrows during the whole sentence; only this non-manual form distinguishes the corresponding statement from the question.

Figure 3 Initial, medial, and final stage of the NGT sign TREE, showing the articulation of the Dutch word [bo:m] 'tree.'

It is this use of non-manual features that gives rise to the comparison with prosody in spoken languages: Question intonation in languages such as English and Dutch also consists of a pattern (of pitch movement) that is 'overlaid' on the lexical and grammatical content of the sentence. Sentence types that are marked by non-manual features in sign languages studied to date include yes–no questions, wh-questions, negations and affirmations, topic–comment structures, and conditionals. One of the ongoing theoretical debates in the literature centers around the source of non-manual markers such as head shakes in negative constructions: are they directly generated by the syntactic structure, or are they prosodic features that are the indirect result of certain semantic–syntactic features? If the latter would be the case, one predicts that the alignment of the non-manual feature in time coincides with a prosodic domain, which may not always be isomorphic to the relevant syntactic domain that is the source of the feature. Another open question concerns the grammatical specificity of markers such as those used in questions: Are they perhaps pragmatic markers with a more general function in the interaction, rather than being specified syntactically?

From one of the first larger typological studies on sign languages, it clearly appears that sign languages do not uniformly recruit non-manual mechanisms for the same semantic or syntactic structures in the same way. Zeshan (2004) showed that interrogative constructions in sign languages in different areas of the world feature different combinations of manual and non-manual markers. Non-manual features were found to universally accompany yes–no questions but are not used to the same extent in wh-questions across languages.

The direction of eye gaze has been claimed to play a role in expressing syntactic agreement in ASL (Bahan, 1996). In BSL, eye gaze is used at different levels of the grammar, including phonology (lexical distinctions) and regulating the interaction between signer and addressee (Sutton-Spence and Woll, 1999). In NGT, eye contact with the interlocutor occurs consistently on focused constituents.

For ASL, Wilbur and Patschke (1998) argued that forward and backward leans of the body (and/or head) function as a marker of contrasting categories. This feature is found in the lexicon, distinguishing a sign such as ONLY (backward lean) from ALSO (forward lean). At a syntactic–pragmatic level, backward leans may signal restrictive focus marking, whereas forward leans can be associated with expanding focus. Thus, the use of leans also extends to pragmatics and discourse and is not confined to realizing syntactic distinctions.

Eye blinks of different duration are hypothesized to be correlated to linguistic structure in some way. Rapid periodic eye blinks may have a boundary marking function, typically occurring between rather than within sentences. On the other hand, longer ('voluntary') eye blinks may have a semantic impact in sign languages such as ASL, expressing emphasis, for example.

A large set of non-manual features is related to 'role-taking' in sign languages, marking direct speech.

Figure 4 Sentence translation: ''My brother came up to me, and said, 'what are you doing?!' I replied, 'I'm just working.' He said, 'well hurry up!' I said 'OK,' and continued my work.'' (Left) Taking the role of the brother, who is conceptualized as standing to the right of the signer (who is conceptualized as being seated). (Right) Taking the role of the signer, who is seated.

After establishing the location of a referent in signing space, eye gaze, head movement, and body movement can all be used to take on the role of one of the referents while signing a sentence. In many cases, the different non-manual features are used in tandem. Interestingly, the role of a referent can also be indicated by mimicking physical or emotional properties of the referent, such as a bent-forward position in which he or she is seated or an angry facial expression. Liddell (2003) discussed these combinations of linguistic and seemingly extralinguistic (or 'gestural') expressions in more general terms. An example is presented in Figure 4.

In NGT, the role of a referent is typically indicated by turning the head left or right, and this can be accompanied by reinforcing motion of the upper body. However, depending on the context, it is also possible to use upward and downward rotation of the head. This occurs in distinguishing parents (relatively tall) from children (relatively low), but it can also be used for people of identical height who happen to be located at different heights in a specific context that the signer reports about – for example, one person seated and the other standing (as in the example in Figure 4). In addition, this height difference is used metaphorically in some sign languages, distinguishing people with low and high status, and it can be marked by other non-manual features such as the gaze direction.

As in spoken language interaction, non-manual cues are also involved in providing feedback from the addressee to the signer and in regulating the interaction between the participants in a conversation.

Methodological Note

There are few, if any, quantitative studies of non-manual aspects of sign languages using data from measurements. Studies have typically relied on transcription of categories that were considered to be functionally relevant. Most researchers have composed their own transcription system, and there has not been any standardization to speak of. One of the few well-documented linguistic transcription systems is the Edinburgh Non-manual Coding System (ENCS; Colville *et al.*, 1984). The Facial Action Coding System (FACS; Ekman *et al.*, 2002) has also been used. FACS is a narrow phonetic transcription system for facial expressions developed for psychological research on the expression of emotion in the face. This system is very time-intensive to learn and use, and it has primarily been used in some early studies of ASL (Baker-Shenk, 1983).

Nonmonotonic Inference

In most logical systems, inferences cannot be invalidated simply by the addition of new premises. If an inference can be drawn from a set of premises *S*, then it can also be drawn from any larger set incorporating *S*. The truth of the original premises guarantees the truth of the inferred conclusion, and the addition of extra premises cannot undermine it. This property is known as *monotonicity*. (The term is a mathematical one; a monotonic sequence is one whose terms increase but never decrease, or vice versa.) *Nonmonotonic* inference lacks this property. The conclusions drawn are provisional, and new information may lead to the withdrawal of a previous conclusion, even though none of the original premises is retracted.

Much of our everyday reasoning is nonmonotonic. We frequently jump to conclusions on the basis of partial information, relying on rough generalizations – that people usually mean what they say, that

Nonmonotonic Inference

K Frankish, The Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

In most logical systems, inferences cannot be invalidated simply by the addition of new premises. If an inference can be drawn from a set of premises *S*, then it can also be drawn from any larger set incorporating *S*. The truth of the original premises guarantees the truth of the inferred conclusion, and the addition of extra premises cannot undermine it. This property is known as *monotonicity*. (The term is a mathematical one; a monotonic sequence is one whose terms increase but never decrease, or vice versa.) *Nonmonotonic* inference lacks this property. The conclusions drawn are provisional, and new information may lead to the withdrawal of a previous conclusion, even though none of the original premises is retracted.

Much of our everyday reasoning is nonmonotonic. We frequently jump to conclusions on the basis of partial information, relying on rough generalizations – that people usually mean what they say, that

machines usually work as they are designed to, that objects usually stay where they are put, and so on. We treat these conclusions as provisional, however, and are prepared to retract them if we learn that the cases we are dealing with are atypical. To take an example that is ubiquitous in the literature, if we know that Tweety is a bird, then we may infer that Tweety flies, since we know that birds typically fly, but we shall withdraw this conclusion if we learn that Tweety is an atypical bird – a penguin, say.

An important feature of inferences like this is that they are sensitive to the absence of information as well as to its presence. Because we lack information that Tweety is atypical, we assume that he is not and proceed on that basis. (That, of course, is why the acquisition of new information can undermine the inference.) In standard logics, by contrast, inference is sensitive only to information that is explicitly represented, and we would need to add the premise that Tweety is not atypical in order to reach the conclusion that he flies. This feature of nonmonotonic inference makes it highly useful. We do not have the time or mental capacity to collect, evaluate, and process all the potentially relevant information before deciding what to do or think. (Think of everything we would need to know in order to be sure that Tweety is not atypical – that he is not a penguin, not an ostrich, not a hatchling, not injured, not tethered to the ground, and so on.)

Because of its central role in commonsense reasoning, nonmonotonic inference has attracted much interest from researchers in artificial intelligence – in particular from those seeking to model human intelligence in computational terms. The challenge has been to *formalize* nonmonotonic inference – to describe it in terms of a precisely defined logical system that could then be used to develop computer programs that replicate everyday reasoning.

Nonmonotonic logic also has applications to more specific problems in artificial intelligence, among them the so-called *frame problem* (McCarthy and Hayes, 1969; *see also* **Frame Problem**). In order to plan how to reach its goals, an artificial agent will need to know what will and what will not change as a result of each action it might perform. But the things that will *not* change as a result of an action will be very numerous, and it would be impracticable to list them all in the system's database. A more efficient solution would be for the system to reason nonmonotonically, using the rule of thumb that actions leave the world unchanged except in those respects in which they are known to alter it. Another application is in the area of database theory. Here it is often convenient to operate with the tacit assumption that a database contains all the relevant information and to treat as false any proposition that cannot be proved from it. This is known as the *closed world assumption* (Reiter, 1978). Again, this involves a nonmonotonic inference relation, since the addition of new data may permit the derivation of a proposition that was previously underivable and had thus been classified as false. Further areas of application include reasoning about natural kinds, diagnostic reasoning, and natural language processing (Reiter, 1987; McCarthy, 1986).

Work on formalizing nonmonotonic inference has progressed rapidly since its beginnings in the 1970s, and there is now a large body of mature work in the area, much of it highly technical in character. (For a collection of seminal papers, see Ginsberg, 1987; for surveys of the field, see Brewka *et al.*, 1997, and the articles in Gabbay *et al.*, 1994. Antoniou, 1997, offers a relatively accessible introduction to the area.)

One of the most important nonmonotonic formalisms is *default logic*, developed by Raymond Reiter (1980). This involves supplementing first-order logic with new rules of inference called *default rules*, which have the form in (1).

(1) $\dfrac{p : q}{r}$

P is known as the *prerequisite*, q as the *justification*, and r as the *consequent*. Such rules are to be read, 'If p, and if it is consistent with the rest of what is known to assume that q, then conclude that r.' In simpler cases ('normal defaults'), q and r are the same, so the rule says that given the prerequisite, the consequent can be inferred, provided it is consistent with the rest of one's data. Thus the rule that birds typically fly would be represented as (2).

(2) $\dfrac{Bird(x) : Flies(x)}{Flies(x)}$

This says that if x is a bird and the claim that x flies is consistent with what we know, then we can infer that x flies. Given that all we know about Tweety is that he is a bird, we can therefore infer that he flies. The inference is nonmonotonic, since if we subsequently acquire information that is inconsistent with the claim that Tweety flies, then the rule will cease to apply to him.

The application of default rules is tricky, since it is necessary to check their justifications for consistency not only with one's initial data but also with the consequents of any other default rules that may be applied. The application of one rule may thus block that of another. To solve this problem, Reiter introduced the notion of an *extension* for a *default theory*. A default theory consists of a set of premises W and a set of default rules D. An extension for a default

theory is a set of sentences E that can be derived from W by applying as many of the rules in D as possible (together with the rules of deductive inference) without generating inconsistency. An extension of a default theory can be thought of as a reasonable development of it.

Another approach, one closely related to default logic, is *autoepistemic logic* (Moore, 1985). This turns on the idea that we can infer things about the world from our introspective knowledge of our own minds (hence the term 'autoepistemic'). From the fact that I do not believe that I owe you a million pounds, I can infer that I do not owe you a million pounds, since I would surely know if I did. Building on this idea, autoepistemic logic represents rules of thumb as implications of claims about one's own ignorance. For example, the rule that birds typically fly can be represented as the conditional claim that if something is a bird and one does not believe that it *cannot* fly, then it does fly. Given introspective abilities, one can use this claim to draw the defeasible conclusion that Tweety flies, based on one's ignorance of reasons to think he cannot. This approach can be formalized by using the apparatus of modal logic, with the modal operator L interpreted as 'It is believed that.'

A third approach is *circumscription* (McCarthy, 1980, 1986; see also Lifschitz, 1994). This involves formulating rules of thumb with abnormality predicates and then restricting the extension of these predicates – *circumscribing* them – so that they apply to only those things to which they must apply, given the information currently available. Take the Tweety case again. We render the rule of thumb that birds typically fly as the conditional in (3), where 'Abnormal' signifies abnormality with respect to flying ability.

(3) $\forall x(Bird(x) \,\&\, \neg Abnormal(x) \rightarrow Flies(x))$.

This does not, of course, allow us to infer that Tweety flies, since we do not know that he is not abnormal with respect to flying ability. But if we add axioms that circumscribe the abnormality predicate so that it applies to only those things that are currently known to be abnormal in this way, then the inference can be drawn. This inference is nonmonotonic, since if we were to add the premise that Tweety *is* abnormal with respect to flying ability, then the extension of the circumscribed predicate would expand to include Tweety, and the inference would no longer go through. Unlike the other strategies mentioned, circumscription can be formulated by using only the resources of first-order predicate calculus, though its full development requires the use of second-order logic, allowing quantification over predicates.

Each of these approaches has its own strengths and weaknesses, but there are some general issues that affect them all. One problem is that all of them allow for the derivation of multiple incompatible sets of conclusions from the same premises. In default logic, for example, a theory may have different extensions depending on the order in which the rules are applied. The standard example is the theory that consists of the premises *Nixon is a Quaker* and *Nixon is a Republican*, together with the default rules *Quakers are typically pacifists* and *Republicans are typically not pacifists*. Each of these rules blocks the application of the other, since the consequent of one is incompatible with the justification of the other. The theory thus has two incompatible extensions – one in which the first rule is applied and containing the conclusion that Nixon is a pacifist, the other in which the second rule is applied and containing the conclusion that Nixon is not a pacifist. Similar results occur with the other approaches mentioned.

The existence of multiple extensions is not in itself a weakness – indeed, it can be seen as a strength. We might regard each extension as a reasonable extrapolation from the premises and simply plump for one of them. (This is known as the *credulous* strategy. The alternative *skeptical* strategy is to endorse only those claims that appear in every extension.) In some cases, however – particularly in reasoning involving time and causality – a plausible theory generates an unacceptable extension. Much work has been devoted to this problem – one strategy being to set priorities among default rules, which determine the order in which they are applied and so restrict the conclusions that can be drawn. (A much-discussed case is the *Yale shooting problem*, introduced in Hanks and McDermott, 1987, where the rule of thumb that living things typically stay alive generates an unexpected conclusion in reasoning about the effects of using a firearm. For a description of the scenario, *see* **Frame Problem**, and for discussion, see Shanahan, 1997.)

A second problem concerns implementation. The goal of much work in this area is to build artificial nonmonotonic reasoning systems, but the formal approaches that have been devised are not easy to implement. Default logic, for example, requires checking sets of sentences for consistency, and there is no general procedure for computing such checks. Restricted applications have been devised, however, and aspects of nonmonotonic reasoning have been effectively implemented by using the techniques of *logic programming* (programming in languages based on formal logic).

A third issue concerns the piecemeal character of much work in this area. Theories have been developed

and elaborated in response to particular problem cases and with relatively little attention to the features of the inference relations they generate. Recent work has begun to address this issue and to identify properties that are desirable in any nonmonotonic inference relation (see, for example, Makinson, 1994). One of these is that adding a conclusion back into the premise set should not undermine any other conclusions – a property known as *cautious monotonicity*.

Finally, a word about probabilistic logics. Most nonmonotonic formalisms embody a *qualitative* approach: premises and conclusions are treated as either true or false, as in deductive logic. But probabilistic logics, in which propositions are assigned continuous probability values, can also be used to model certain types of nonmonotonic inference. In probabilistic reasoning, it is common to treat a conclusion as warranted if its probability, given the premises, exceeds a certain threshold. This inference relation is nonmonotonic, since the addition of new premises may lead to a readjustment of one's probability assignments, with the result that a conclusion that previously passed the threshold now falls short of it. However, although probabilistic logics are well suited for modeling reasoning under uncertainty (see Shafer and Pearl, 1990), it is unlikely that they can do all the work required of a theory of nonmonotonic inference (McCarthy, 1986).

Nonmorphological Word Formation

Introduction

With the exception of those terms created by word manufacture, the items described here result from applying reduction mechanisms; however, what is shortened is not actually a morph, a lexeme, or a base but rather a word-form, that is, the phonological or orthographic shape adopted by a word whenever it occurs. Orthoepic, phonotactic, or purely orthographic constraints, which are to a great extent unsystematic and language-specific, play an important role in the creation of these items; that explains why they are often regarded as marginal or unpredictable and also why the attempts at describing and categorizing them usually end up in vague overlapping definitions, complex taxonomies, or chaotic lists of irregularities.

On the whole, clippings, initialisms, and abbreviations are the result of shortening phonological and/or

and elaborated in response to particular problem cases and with relatively little attention to the features of the inference relations they generate. Recent work has begun to address this issue and to identify properties that are desirable in any nonmonotonic inference relation (see, for example, Makinson, 1994). One of these is that adding a conclusion back into the premise set should not undermine any other conclusions – a property known as *cautious monotonicity*.

Finally, a word about probabilistic logics. Most nonmonotonic formalisms embody a *qualitative* approach: premises and conclusions are treated as either true or false, as in deductive logic. But probabilistic logics, in which propositions are assigned continuous probability values, can also be used to model certain types of nonmonotonic inference. In probabilistic reasoning, it is common to treat a conclusion as warranted if its probability, given the premises, exceeds a certain threshold. This inference relation is nonmonotonic, since the addition of new premises may lead to a readjustment of one's probability assignments, with the result that a conclusion that previously passed the threshold now falls short of it. However, although probabilistic logics are well suited for modeling reasoning under uncertainty (see Shafer and Pearl, 1990), it is unlikely that they can do all the work required of a theory of nonmonotonic inference (McCarthy, 1986).

Nonmorphological Word Formation

Introduction

With the exception of those terms created by word manufacture, the items described here result from applying reduction mechanisms; however, what is shortened is not actually a morph, a lexeme, or a base but rather a word-form, that is, the phonological or orthographic shape adopted by a word whenever it occurs. Orthoepic, phonotactic, or purely orthographic constraints, which are to a great extent unsystematic and language-specific, play an important role in the creation of these items; that explains why they are often regarded as marginal or unpredictable and also why the attempts at describing and categorizing them usually end up in vague overlapping definitions, complex taxonomies, or chaotic lists of irregularities.

On the whole, clippings, initialisms, and abbreviations are the result of shortening phonological and/or

orthographic words in different degrees with respect to length and complexity. Clippings (e.g., *lab* for *laboratory*) are medium-size (i.e., usually syllable-based) shortenings initially involving the phonological shape of a word, which then develops a graphic version with occasional spelling adjustments. Initialisms (e.g., *laser, BBC*) are the result of maximal reduction plus minimal fusion (i.e., the simple concatenation of constituents). They are originally graphic, but develop a phonic version. Last, abbreviations are exclusively graphic shortenings, thus having no place in morphological description. Nevertheless, their categorization as a homogeneous group is difficult because some may evolve to clippings (e.g., *Inc*: for *Incorporated*) or to initialisms (e.g., *F.O.B./f.o.b.* for *free on board*), or stay in between as fluctuating hybrids. In the same way, a discrete treatment of complex (both graphic and phonic) shortenings is prevented by the existence of an increasing number of cases of difficult ascription that approach the periphery of typical blends (the product of medium to minimal reduction and maximal fusion, such as *motel*), for instance, English *Satcoma* (for *Satellite Communications Agency*) and Russian *SMERSH/Smersh* (for *Smert Shpionam* 'death to spies', a section of the KGB).

Shortening

Splinter-Based Shortenings: Clippings (*lab*, *phone*)

In the present case, the term splinter refers to those graphic and phonemic sequences that are neither morphs (e.g., *-ness*) nor combining forms (e.g., *electro-*), and whose length generally allows their identification as belonging to a previous word. Consequently, splinters tend to be syllables or units larger than syllables in their sources, such as *Digi-* and *-alt* in *Digiralt* (from *digital radar altimeter*), although that is not always the case; note, for instance *smo-* and *-og* in *smog* (from *smoke* and *fog*).

Clipping is the process by which a word-form of usually three or more syllables is shortened without a change in meaning or function. Clipped forms often convey informal or affectionate connotations; sometimes, however, widespread use can cause them to replace their sources and therefore lose their informal quality, as in English *pram* (from *perambulator*) and French *vélo* (from *vélocipède*) 'bike'. Familiarity and affection are particularly displayed in reduced forms of proper names, such as Spanish *Lupe* (*Guadalupe*), German *Uli* (*Ulrich*), and English *Rick* or *Ricky* (*Richard*).

On the whole, and as Kreidler (1979: 29) points out, this device is basically characterized by unpredictability, particularly as regards "the precise shape of the shortening" and "where the cut will be made." The process often ignores morphemic boundaries, as in English *(heli)copter*, French *ordi(nateur)* 'computer,' or German *Abo(nnement)* 'subscription.' General trends can, however, be inferred from the analysis of existing items; Spanish, for example, exhibits a clear tendency toward syllable-based, vowel-ended clipping. Accordingly, prototypical clippings are partial shortenings of simple word-forms, their lexical categories being usually nouns or adjectives. The most typical clippings have one or two syllables left and only one stress. Because their sources are often tri- or polysyllabic, their degree of shortening can be described as typically medium. The process may affect either the final part of the source (i.e., 'hind' clipping), as in Polish *pozdr(owienia)* 'greetings' and Japanese *anbiri (baburu)* (the borrowing of English *unbelievable*), or the beginning of the source (i.e., 'fore' clipping), as in Spanish *(violon)chelo* 'violincello', with plural morphs being retained if present in the sources, as in English *spec(tacle)s*. Minor spelling adjustments do not affect the centrality of the items, for example, English *mike* (from *microphone*) or French *sensass* (from *sensationnel* 'fantastic'). These adjustments may include the replacement of final vowel letters, as in Spanish *forasta* (from *forastero* 'foreigner'), French *apéro* (from *apératif* 'cocktail'), and English *ammo* (from *ammunition*), or the addition of hypocoristic suffixes *-y/-i/-ie*, as in English *comfy* (from *comfortable*) and German *Hausi* (from *Hausaufgabe* 'homework').

The shortening of both ends – for instance, English *(in)flu(enza)* or *(de)tec(tive)* – is far less frequent and therefore results in less typical items. Other instances of still central but not prototypical clippings as regards source unit and type of shortening are those having a source form other than one simple word-form, such as English *fed*(*eral government employee*) and *pub*(*lic house*), French *beauf* (from *beau-frère* 'brother-in-law') and *d'acc* (from *d'accord* 'OK'), and Spanish *porfa* (from *por favor* 'please'), and also midclippings, that is, items in which the shortening affects the middle of the source form, for instance, English *corti(co)s(ter)one* and *proc(ura)tor.*

In contrast with prototypical and central cases, peripheral clippings exhibit some outstanding irregularities as far as spelling, shortening, source form, and use. Some peripheral clippings are respelled items with extensive modifications, such as English *brolly* (from *umbrella*) and French *hosto* (from *hôpital* 'hospital'); there are also peripheral items in which the remaining part is a full word-form as in (*lysergic*) *acid* (*diethylamide*)or *soap*(*opera*); in other cases, peripherality arises from contextual or semantic restrictions: for example, English *optical* is shortened only in *op art*, and French *politiques* is shortened only in *les*

sciences po 'political science'; similarly, *examination* becomes *exam* only with an academic meaning.

Finally, it would be possible to classify as quite marginal clippings some items mainly used orally and only in certain contexts; actually, they are instances of three types of phonetic elision sometimes called aphaeresis (phonetic fore clipping), syncope (phonetic midclipping), and apocope (phonetic hind clipping), for example '*fraid* (from *afraid*), '*deed* (from *indeed*), and *o'er* (from *over*). In writing, these truncations are usually marked by means of apostrophes.

Letter-Based Shortenings (Initialisms): Alphabetisms (*NBC*) and Acronyms (*laser*)

The superordinate term initialism is intended to refer to both the method of formation and the graphic origin of these items: An initialism is, therefore, the result of selecting the initial letter, or occasionally the first two letters, of the orthographic words in a phrase and combining them to form a new sequence. Free forms with no lexical meaning, such as prepositions and conjunctions, are usually excluded. The new item can be pronounced as a word (prototypical acronyms), as in Italian *Fiat/FIAT* (from *Fabbrica Italiana Automobili Torino* 'Italian Motorworks in Turin'); as a series of letter names (prototypical alphabetisms), as in Tagalog *MGB* (from *Magadang Gabi Bayan* 'Good Evening People', a TV show); in both ways, as in English *VAT/Vat* (from *Value Added Tax*); as some combination of the two, as in Spanish *PSOE* (from *Partido Socialista Obrero Español*, a political party), pronounced /pe'soe/ or /'soe/, and English *VJ/VeeJay* (from: *Video-Jockey*); or even display idiosyncratic pronunciations, as in English *SWF* (from *Shockwave Flash File*), read [swɪf]. The choice of letters and pronunciation is due to a variety of factors, such as the number and location of vowel letters in the item, the phonotactics of the language, the need to obtain (or avoid) an already existing phonic and/or graphic word-form, stylistic conditions, and the speaker's familiarity with the form and the expanded expression it replaces. An increasingly popular pattern for the creation of acronyms consists in building the expanded expression around the constituent letters of a word previously selected, as in *ASH* (for *Action on Smoking and Health*).

The lexicalization of initialisms consists of a combination of parallel processes: in pronunciation, a development from expanded to letter-by-letter and finally orthoepic reading; graphically, a change from capitals (with or without periods) to small letters; morphologically, the acceptance of inflectional and derivational morphemes; and semantically, the replacement of the original expanded expression (which is the only associated meaning those forms initially have) with semantic features that have arisen from their use as common nouns.

In contrast with the regular behavior of alphabetisms, the orthoepic requirements of acronyms allow some freedom in the selection of initials, thus adding to the complexity of the category. Less central acronyms result from recurrent irregularities in the selection of constituents, for example, *DISPLAY* (from *Digital Service Planning Analysis*). As regards peripheral acronyms, the most interesting deviations include constituents with medium, minimum, or even no shortening. The dividing line between acronyms and blends tends to blur when splinters are selected as constituents, either alone or in combination with one or more letters that are not necessarily initials. Consider the examples in Table 1.

Similarly, central but not prototypical alphabetisms comprise items displaying irregularities in the choice of initials, forms whose source is a word instead of a phrase, for example, *ECG* (from *electrocardiogram*), or items with a written alternative in lowercase, such as *CIF/c.i.f.* (from *cost, insurance, and freight*). Peripheral alphabetisms include extraneous or uncommon constituents such as numbers, symbols, full word-forms, or letters indicating series, phases, or types, as in *US of A* (from *United States of America*) and *UVA* (from *ultraviolet A*). They may also lack a source form, for example, *KLF* or *LFO* (both names of pop music groups).

Initialization is also present in letter compounds, that is, combinations of one initial (or, at most, two)

Table 1 Acronyms or blends?

Example	*Language*	*Full phrase*	*Meaning*
Gulag	Russian	Glavnoye Upralevniye Lagerei	'Soviet prison and labor camp system'
Ma'âlî	Arabic	Mu'jam al-'Arabiyya l-'âlî	'Electronic Arabic Dictionary'
Ekubang	Indonesian	Ekonomi, Keuangan dan Pembangunan	'Economics, Finance and Development'
AFNOR	French	Association Française de Normalisation	'French Standards Organisation'
COPCON	Portuguese	Comando de Operaçoes do Continente	'Continental Operations Command'
SAPHYDATA	English	Systems for Acquisition, Transmission and Processing of Hydrological Data	

and one full form, such as English *e(lectronic)-mail*, Spanish *bomba H* 'H(ydrogen) bomb', and German *SB-Tankstelle:* 'self-service gas station' (*SB* from *Selbstbedienung* 'self-service'). Although the initial often replaces a word-form, it may also be iconic (as in *T-shirt*) or simply reduplicate the first letter of the following word-form (*H-hour*).

The Bridge toward Neighboring Categories

The Periphery of Blends and Compounds: Clipped Compounds (*Op-Ed* from *opposite-editorial* page) Because blends are obtained by joining two or more word-forms through simple concatenation or overlap and then shortening at least one of them, clipped compounds can be regarded as a peripheral type of blends composed of initial splinters joined with a low degree of phonic integration, that is, with simple concatenation, as in English *fro-yo* (from *frozen yogurt*). Syllable-based clipped compounds are the closest equivalent to native initialisms in languages traditionally classified as analytic or isolating, such as Chinese, Korean, and Indonesian, for example, Chinese *Beijing da xue* 'North-capital big school' (that is, Peking University) becomes *Beida* 'North-big' and Indonesian *tahanan politik* 'political prisoner' is shortened to *tapol*. Compound loanwords are also usually reduced in this way in Japanese, thus *hangaa-sutoraiku* (the borrowing of English *hunger strike*) becomes *han-suto*.

The Periphery of Abbreviations: Unexpanded Items Items lying between abbreviations and clippings fall into several types, although they could all be described as unexpanded abbreviations. The most important group comprises a set of hybrids with two possible readings, expanded like abbreviations and unexpanded like clippings, the latter reading having informal connotations, for example, English, *Co* (from *Company*). In the same way as proper abbreviations, these items may exhibit alternative spellings with periods.

As regards the borderline between alphabetisms and abbreviations, the speaker's habits, background knowledge, and style (*see* **Style and Style Shifting**) play an important role in the choice of unexpanded or expanded readings. Three basic types of fluctuating forms can be distinguished: items in capitals with two possible readings (expanded and unexpanded), as in *LA*(*Los Angeles*); items in lowercase with two readings, as in *cps* (*cycles per second*); and items with two spellings and two readings, as in *ETD/e.t.d.* (*estimated time of departure*).

Word Manufacture

In comparison with the number of words created from already-existing bases or word-forms, the number of items resulting from word manufacture is quite limited. There are basically two types to be distinguished: motivated and *ex nihilo*. In the former, the creation of the new word seems to follow some discernible logic, for example, because the item has been formally or semantically inspired by an already-existing word (compare Tolkien's *hobbit* and *rabbit*). However, the purest cases of non-morphological word formation result from creating a new item with no morphological, phonological, or orthographic motivation, that is, *ex nihilo*. Most of these items are either commercial, for example, *Kodak,* or literary, for instance, *grok* 'to communicate sympathetically' (invented by Robert Heinlein in his novel *Stranger in a Strange Land,* 1961) and *quark* (first used in James Joyce's *Finnegan's Wake,* 1939); see Bauer (1983). Further examples of this type of word manufacture are *googol* (a word coined by the nephew of the American mathematician Edward Kasner, who used it to refer to the numeral 1 followed by 100 zeros), *Krámpack* (a Spanish movie title intended to mean 'mutual masturbation'), and *Bersuit* (the name of a rock band).

Nonnative Speaker Teachers

K K Samimy, The Ohio State University, Columbus, OH, USA

Introduction

Although the statistics on the number of English users in the world vary widely depending on which scholars are reporting in the field, Strevens (1992) maintains that more than one and a half billion people use English around the world as a first, second, or foreign language. One fourth of the total users are native speakers, whereas the remaining majority use English as a second or foreign language. Kachru (1989) conceptualizes three concentric circles according to the different roles that English plays in different countries: (1) the Inner Circle, where English is spoken as the first language in countries such as the United States, Australia, the United Kingdom, and Canada, (2) the Outer Circle, where English is used as a second language in a multilingual setting in countries such as the Philippines, India, and Singapore, and (3) the Expanding Circle, where English is studied as a foreign language such as in Japan, Korea, and China. In the Inner Circle, it is estimated that 320–380 million people use English as their first language, whereas 150–300 million people use it as their second language in the Outer Circle. In the Expanding circle, 100–1000 million people are estimated to use it as a foreign language. To summarize, Kachru (1996: 241) states that "there are now at least four non-native speakers of English for every native speaker". Similarly, Graddol (1999) projects that during the next 50 years the balance between native speakers and non-native speakers will shift critically with non-native speakers eventually overtaking native speakers.

Traditionally, English teachers in the Outer Circle and the Expanding Circle have been considered as non-native speakers of English or teachers who share the same cultural and linguistic backgrounds with their students. As the number of English users increases in these two circles, the education of non-native English speaking teachers (non-NESTs) becomes critical. Braine (1999) states that the place of native and non-native speakers in teaching English has always been an issue since English was taught internationally, however, interest in non-NESTs is a fairly recent phenomenon. Since his seminal book, *Non-native educators in English language teaching* was published in 1999, there has been tremendous interest in non-native speaker issues among researchers and practitioners in Teachers of English to Speakers of Other Language (TESOL). Although the issues related to non-NESTs have been studied widely, in this article three areas of research will be highlighted and discussed: (1) definitions of native and non-native speakers, (2) non-NESTs' perceptions of their status and roles, and (3) professional development of non-NESTs. Based on the discussion over these areas, recommendations for future research also will be made.

Definitions of Native and Non-native Speakers

Defining a native speaker and a non-native speaker has been a controversial issue in applied linguistics. Davies (1991) asserts that the definition of a native speaker tends to be circular in that the native speaker is defined as he or she who is perceived as NOT being a non-native speaker, whereas the non-native speaker is defined solely as being a non-native speaker. Some common characteristics associated with being a native speaker of a language, according to Rampton (1990: 97), include the following:

1. A particular language is inherited, either through genetic endowment or through birth into the social group stereotypically associated with it.
2. Inheriting a language means being able to speak it well.
3. People either are or are not native/mother-tongue speakers.
4. Being a native speaker involves the comprehensive grasp of a language.
5. Just as people are usually citizens of one country, people are native speakers of one mother tongue.

More recently, Davies devoted his entire book to demystify the construct of a native speaker both psycholinguistically and sociolinguistically. In his recent book, *The native speaker: myth and reality*, Davies provides six attributes of a native speaker (2003: 210–211):

1. Childhood acquisition: The native speaker acquires the L1 of which s/he is a native speaker in childhood.
2. Intuitions about idiolectal grammar (Grammar 1): The native speaker has intuitions (in terms of acceptability and productiveness) about his/her own language.
3. Intuitions about group language grammar (Grammar 2): The native speaker has intuitions about those features of which are distinct from his/her Grammar 1.

4. Discourse and pragmatic control. The native speaker has a unique capacity to produce fluent spontaneous discourse. . . . In both production and comprehension the native speaker exhibits a wide range of communicative competence.
5. Creative performance. The native speaker has a unique capacity to write creatively.
6. Interpreting and translating. The native speaker has a unique capacity to interpret and translate into the L1 of which s/he is a native speaker.

How does a L2 user compare with the native speaker in terms of these attributes? Can she/he become a native speaker of the target language? Using the same criteria, Davies asserts that all except the first criterion, 'childhood acquisition,' are contingent issues. In his own words, "The answer to the question of L2 learners evolving into native speakers of the target language must therefore be 'Yes': but the practice required, given the model of the children L1 acquirer who for five to six years spends much of his or her time learning language alone, is so great that it is not likely that many second-language learners become native speakers of their target language" (p. 212).

In his comparison of a native speaker and a non-native speaker, Medgyes (1992, 1994) considers the native and non-native categories as clearly impermeable. In other words, he maintains that a native speaker's linguistic competence constitutes an "advantage . . . so substantial that it cannot be outweighed by other factors prevalent in the learning situation, whether it be motivation, aptitude, perseverance, experience, education, or anything else" (1992: 342). The non-native speaker, by contrast, has to labor eternally under a "linguistic handicap" (1994: 103) while progressing along the interlanguage continuum. Medgyes sees native speakers as those who "have acquired English in comparison with nonnative speakers who are still acquiring" (p. 12). Even if they acquire "native-like" proficiency, non-native speakers still will be labeled as "pseudo-native speakers" (1994).

Cook (1999), by contrast, challenges the "comparative fallacy" (Bley-Vroman, 1983), in which a non-native speaker's performance is constantly compared with a native speaker's performance. He asserts that "the prominence of the native speaker has obscured the distinctive nature of the successful L2 user and created an unattainable goal for L2 learners (p. 185). In addition, Cook maintains that non-native speakers differ from native speakers in their knowledge of their L2s and L1s and in some of their cognitive processes; hence, we must stop imposing the native speaker norm on non-native speakers and treat them in their own right.

Similarly, Kachru and Nelson (1996) reject the notion of native and non-native dichotomy. They assert that the spread of English in its sociohistorical context has created different varieties of English, along with highly proficient speakers and professionals in English Language Teaching (ELT). To view them through the lens of the native versus non-native dichotomy is to accept "a linguistic caste system and maintain a monocultural and monolingual point of reference (p. 79).

Non-native English-Speaking Teachers' Perceptions of Their Status and Roles

Due to the growing awareness of the large number of non-native teachers working in the ELT field worldwide, researchers started to examine their perceived status and/or roles in relation to native English-speaking teachers (NESTs) (e.g., Medgyes, 1992; Samimy and Brutt-Griffler, 1999; Seidlhofer, 1999; Tang, 1997). Some scholars retain the difference in NESTs' and non-NESTs' professional expertise (Medgyes, 1992; Reves and Medgyes, 1994; Arva and Medgyes, 2000). This dichotomous position, however, has been questioned by other scholars due to the complexity involved in ELT professional expertise (e.g., Brutt-Griffler and Samimy, 1999; J. Liu, 1999).

In a series of studies, Medgyes and his colleagues examined non-NESTs' unique features as ELT professionals in comparison to native teachers. Medgyes (1992), for example, investigated non-NESTs' perceived difficulties in the use of English and differences in teaching behavior between the two groups of teachers. The findings, through questionnaires obtained from approximately 220 native and non-native teachers in 10 countries, showed that most teachers viewed their teaching approaches as different mainly due to discrepancies in their linguistic competence. However, Medgyes also points out that non-NESTs have equal opportunities of becoming as effective as NESTs because the former possesses teaching strengths derived from being successful English learners. These strengths are, for example, to "serve as imitable models," "teach learning strategies more effectively," "anticipate language difficulties," "provide learners with more information about the English language," "show more empathy to their students," and "share the learners' mother tongue" (pp. 346–347). For implications, therefore, Medgyes suggests that the different roles in teaching practices between NESTs and non-NESTs should be acknowledged. He also encourages collaborative teaching between the two types of teachers to balance their respective strengths and weaknesses.

In a similar vein, Reves and Medgyes (1994) examined the relationship among non-NESTs' English proficiency, their teaching behavior, and their self-image as English teachers. They delivered questionnaires to 216 ELT teachers in 10 countries, among which about 90 percent of the participants were non-native teachers. Based on their findings, Reves and Medgyes argue that the factors such as "non-NESTs' teaching qualifications," "the time non-NESTs spent in an English speaking country," and "the frequency of non-NESTs' contact with NESTs" would affect non-native teachers' self-images and their ways of teaching (p. 357). The authors, therefore, emphasize the importance of non-NESTs' "frequent exposure to an authentic native language environment and proficiency-oriented in-service training activities" to improve their self-image (p. 364).

Arva and Medgyes (2000) further expanded the previous research and compared actual teaching behavior of five NESTs and five non-NESTs in Hungarian secondary schools. Unlike the previous studies, the data were collected through interviews and classroom observations. The researchers found several differences between the two groups of teachers which included the following: (1) NESTs had superior English language competence; (2) non-NESTs were more confident about grammatical knowledge; (3) NESTs lacked the ability to speak the students' native language; (4) NESTs adopted more flexible teaching approaches; and (5) NESTs supplied more cultural information about English speaking countries. Arva and Medgyes argue that these differences in their teaching behavior can be attributed to the linguistic discrepancy between non-NESTs and NESTs. Furthermore, they also maintain the position that each group of teachers is likely to have appropriate roles to play in teaching English. That is, for example, NESTs teach conversation classes, whereas non-NESTs take care of other components such as grammar.

To summarize thus far, Medgyes and his colleagues draw a clear professional distinction between NESTs and non-NESTs in relation to the teachers' linguistic competence. However, some researchers view such distinction as simplistic. Samimy and Brutt-Griffler (1999), for example, explored the perceptions of non-native TESOL graduate students as ELT professionals in relation to native teachers. Seventeen international students who attended a graduate seminar at a university in North America participated in this case study. The findings obtained through multiple data methods (questionnaires, classroom discussion, in-depth interviews, and autobiographical accounts) suggest that the participants perceived themselves differently from native teachers in their English proficiency and in their teaching practices. However, they generally agreed that the question of "who is more successful [native or non-native speakers] depends on learner factors, teacher factors, and contextual factors" (p. 141). Moreover, some of the participants raised a question about the debate over the native versus non-native speaker dichotomy, and argued that major issues of EFL teachers involve the English education curriculum and professional development rather than the lack of native-like proficiency.

Similarly, Seidlhofer (1999) also expresses the danger of a simple transfer from "*competent speaker* to *competent teacher* based on linguistic grounds alone" and the needs to take "cultural, social and pedagogic appropriateness" into account (p. 237). She explains the "double" roles of non-NESTs in the Expanding Circle when they are required to negotiate among competing demands such as the global claims and local realities. Through a careful process of analyzing and mediating competing claims, she emphasizes that teachers can make local decisions for appropriate pedagogy in given contexts. She points out, therefore, that teachers as mediators need to be familiar with not only the target language but also local educational contexts, their students' requirements, and the current development in the research communities relevant to their professions.

J. Liu (1999) also examined non-NESTs' professional issues from the perspectives of seven TESOL professionals and the complexity involved in labeling native and non-native teachers. All participants in this case study were non-NESTs working at the university level in North America. The findings collected through individual interviews revealed that the distinction between the two types of teachers involves various factors such as "precedence in learning languages, competence in the learned language, cultural addition, social identity, and language environments" (p. 85). Moreover, the participants expressed concerns raised by the native versus non-native speaker dichotomy such as "the invisible power relations in the labels" (e.g. hiring process and teaching and learning in the language classroom) (p. 97). Based on the results, Liu argues against the rigid separation between native speakers and non-native speakers and suggests better understanding the complexity involved in the label.

Like Liu, several other researchers have also captured the power relations involved in the label in the Outer and Expanding Circles by investigating non-NESTs' professional identities with comparison to NESTs (e.g., Tang, 1997; Seidlhofer, 1999). Although in both Tang's and Seidlhofer's case studies, non-NESTs acknowledged their strengths as non-native

professionals such as their shared L1 with students and L2 learning experiences, they all clearly expressed their feelings of insecurity or inadequacy due to their perceived low proficiency of English. Both authors, therefore, point out that non-NESTs' self perception had a strong impact on shaping their identities as English teachers.

In summary, this section reviewed the literature examining non-NESTs' self-perceptions of their status and roles as compared to NESTs. The central question about the topic is whether non-NESTs or NESTs are better ELT professionals. Two positions seem prominent on the issue among the scholars. One of the groups of researchers maintains that the distinctive roles between native speakers and non-native speakers need to be acknowledged mainly due to their different language competence (Arva and Medgyes, 2000; Medgyes, 1992; Reves and Medgyes, 1994). The other group of researchers, on the other hand, denies such a sharp division based on linguistic competence because of the multidimensionality of ELT professionals that is shaped by sociocultural and linguistic contexts (Samimy and Brutt-Griffler, 1999) and the complexity that the labels have (J. Liu, 1999).

Few deny the critical role of English language proficiency that English teachers need to have and develop for their professions. In fact, as seen before, some studies examining non-NESTs' professional identities reveal their feelings of insecurity as ELT professionals because of their perceived lower English proficiency as compared to NESTs (Tang, 1997; Seidlhofer, 1999). However, given the various factors involved in ELT professionals, to judge teachers' expertise primarily by language competence as opposed to native speakers seems to be simplistic. In addition, such sharp distinction between the two types of teachers through language competence may demoralize both future and practicing non-NESTs. It also may obscure other similarly critical roles that they need to play as mediators in a given context. Therefore, to acknowledge the multidimensionality of teachers' professional expertise (linguistic, learner, teacher, and social and cultural factors) is critical for non-NESTs' professional success.

Professional Development of Non-native English-Speaking Teachers

English language teachers have experienced high professional demands because of the diverse needs of English learners accompanied by the impact of globalization. To meet these demands, a number of prospective and experienced non-NESTs around the world participate in second language (L2) teacher education programs. Given such circumstances, it is critical to understand non-NESTs' needs for their professional development, on the one hand, and how L2 teacher education programs must be transformed to meet their diverse expectations, on the other hand.

Non-native-Speaking Teachers' Professional Needs and Concerns

The issues of non-NESTs' professional development have gradually received attentions among scholars in the TESOL field. The literature on the topic has revealed their specific professional needs and challenges. Drawing on the various studies on the topic, Kamhi-Stein (2000), for example, describes the four areas which non-NESTs perceive as their needs and concerns in their professions (p. 10):

1. low confidence and self-perceived challenges to professional competence
2. self-perceived language needs
3. lack of voice and visibility in the TESOL profession
4. self-perceived prejudice based on ethnicity or non-native status.

Kamhi-Stein has noted that non-NESTs' perceived low confidence may have an impact on those who are, in particular, studying in English speaking contexts. Samimy and Brutt-Griffler's (1999) case study, for example, reports that, although non-native graduate students considered themselves as successful teachers in their home countries, many questioned their professional competence because of the cultural, educational, and linguistic unfamiliarity involved in the study in the United States. Regarding "self-perceived language needs," several researchers in the TESOL teacher education programs both inside and outside the Inner Circle describe non-NESTs' concerns about the development of their English language proficiency for their professional success (D. Liu, 1999; Carrier, 2003; Murdoch, 1994; Cullen, 1994; Medgyes, 1999). Lack of non-NESTs' voices in the TESOL field is another serious concern (Carrier, 2003; Kamhi-Stein, 1999, 2000; Samimy and Brutt-Griffler, 1999; Thomas, 1999). Samimy and Brutt-Griffler's (1999) case study, for example, demonstrates EFL teachers' awareness of the need to contribute to the TESOL communities with EFL autonomy. Kamhi-Stein (1999) also describes the importance of encouraging non-NESTs to participate in professional conferences in order to raise their voices and status. In terms of "self-perceived prejudice," scholars describe non-NESTs' challenges inside and outside the Inner Circle, especially regarding their credibility as ELT professionals because of their ethnicity and

non-native status (e.g., Amin, 1997; Kamhi-Stein, 1999; Thomas, 1999; Hubbell, 2002). Amin (1997), for example, demonstrates five minority female teachers' perceptions of their students' ideal ESL teachers. The findings through interviews reveal that non-NESTs felt disempowered by their students' strong connection between white native speakers and ideal ESL teachers. In the Expanding Circle, Hubbell (2002) also discusses, in her autobiographical narrative, discriminations that she experienced because of her status as a non-NEST. One of them is an assumption made by administrators and colleagues that NESTs and non-NESTs are assigned different teaching roles, which are conversation classes and required courses respectively, regardless of non-NESTs' English proficiency.

Furthermore, the literature also depicts non-NESTs' concerns about a discrepancy between what they learn in L2 teacher education programs in the Inner Circle and what they may encounter in their teaching practices in their home countries (e.g., Li, 1998; D. Liu, 1999; Pacek, 1996). D. Liu (1999), for example, broadly points out cultural, socioeconomic, and educational differences between the two contexts, and then proposes three areas that the TESOL teacher education programs in the Inner Circle need to address for non-NESTs' professional needs. These areas include: (1) L2 acquisition theories and teaching methodologies relevant and applicable to the EFL contexts, (2) the development of teachers' English language proficiency for their teaching success, and (3) cultural knowledge of English speaking countries.

In addition, focusing on communicative language teaching (CLT), the currently promoted teaching approach in the Expanding Circle for its educational innovation, empirical studies also reveal the difficulties that non-NESTs encounter or perceive in implementing the teaching approach in their classrooms (Li, 1998; Pacek, 1996). Li, for example, examines South Korean secondary school English teachers' perceptions of CLT through questionnaires and interviews. Eighteen teachers who participated in the in-service teacher education program at a Canadian university expressed perceived difficulties such as teacher, student, educational system, and CLT factors to reconcile local realities and the demands expected by the teaching approach. Pacek (1996) also investigated the impact of the one-year U.K. in-service teacher education program sponsored by the Japanese Ministry of Education for Japanese secondary school English teachers to assess its usefulness and practicality. The foci of the program were the improvement of teachers' English proficiency, the understanding of theoretical concepts of teaching approach especially CLT and British culture and society, and its educational system. Forty-three participants who answered the questionnaires expressed their experiences of pressure to mediate local expectations in Japan and what they had learned in the program despite the teachers' positive feedback on the program in general.

Attempts to Meet non-NESTs' Professional Needs in L2 Teacher Education

Although the studies examining how L2 teacher education programs specifically incorporate non-NESTs' issues into the curricula are considerably dearth (Kamhi-Stein, 2000), several teacher educators propose their TESOL program models and/or suggest implications for L2 teacher education (e.g., Brutt-Griffler and Samimy, 1999; Carrier, 2003; Cullen, 1994; Kamhi-Stein, 1999, 2000; Samimy and Brutt-Griffler, 1999). In the Inner Circle, Samimy and Brutt-Griffler (1999), for example, introduce a graduate level seminar, entitled *Issues and Concerns Related to NNS Professionals*, that discusses issues of ELT professionals from different teaching contexts in the TESOL program. Central aims of this seminar were (1) to raise graduate students' critical awareness of the dichotomous discourse of non/native speakers, (2) to develop their identity as ELT professionals, and (3) to promote 'counterdiscourses' regarding cultural assumptions in the center community within the field of applied linguistics and L2 pedagogy. Based on the participants' experiences of a new sense of agency as ELT professionals in the seminar, Samimy and Brutt-Griffler propose more emphasis on "multidimensionality and expertise" than "nativeness or authenticity" in teaching methodologies (p. 142).

Kamhi-Stein (2000) also proposes a different approach, which integrates the discussion on non-NESTs' issues across the curriculum of the TESOL MA program. According to her, central to this "cross-curricular approach" is that both native and non-native student teachers come to understand international students' L2 learning experiences and challenges. Therefore, non-native teacher-trainees re-evaluate themselves as resourceful informants. The approach also aims at helping non-NESTs raise their status with NESTs. To achieve these objectives, Kamhi-Stein introduces activities in and outside the classroom across the curriculum of the program. These activities are reflection on trainees' L2 learning histories to understand their own knowledge and beliefs, web-based discussion to enhance their participation in class, collaborative projects between native and non-native teacher-trainees, and participation in professional conferences to discuss non-native issues.

Most currently, Carrier (2003) proposes "an introductory first semester course" for non-NESTs in

the TESOL program as "a first step" to meet their professional needs. Several key areas emphasized in the course include "contextually responsive teacher education content, training in a different school culture, competing with native English-speaking teacher trainees, self-confidence, and encouraging contributions by non-native teacher trainees to the field of English language teaching" (p. 242). Regarding the contextually responsive content, the course attempts to develop non-NESTs' abilities to evaluate their acquired knowledge in the program for its applicability through assigned readings, class discussions, and course projects relevant to their teaching contexts. With respect to training in a different school culture, the focus is placed on non-NESTs' development of "Western-style academic writing and oral presenting" (p. 245). According to Carrier, teachers' improvement of language proficiency would lead to their self-confidence as ELT professionals and allow other teachers to hear non-NESTs' voices in professional communities.

Furthermore, researchers also make implications for L2 teacher education in the Expanding and Outer circles to meet non-NESTs' professional needs. The central topics of the scholarly discussion seem to be non-NESTs' roles as mediators (Seidlhofer, 1999; Canagaraja, 1999) and their professional expertise, especially regarding language elements (Cullen, 1994; Murdoch, 1994; Medgyes, 1999). In terms of the former, Seidlhofer (1999), for example, stresses non-NESTs' 'double' roles for appropriate pedagogies in a given context when they are required to reconcile the contradictory demands of global claims with the local reality. She then suggests that, in teacher education, EFL teachers need to be encouraged to consider what choices they can make to develop appropriate pedagogy in a given context and how teachers can cultivate their strengths of their double capacity. Canagarajah (1999) also emphasizes teachers' 'double' roles of critically examining and negotiating the inherent tension between local and dominant expectations in the Outer and Expanding Circles. He situated his ethnographic study in "resistance theories" within the critical pedagogical paradigm – that is "there are sufficient contradictions within institutions to help subjects gain agency, conduct critical thinking, and initiate change" (p. 22). Canagaraja, for example, urges teachers to employ ELT teaching beyond the "communicative teaching methods" because of its insensitivity to the reflexivity and its potential role to reinforce the norm. In the reflexive and negotiated process of pedagogy, he argues that there is possibility for developing a "context-sensitive and culture- specific approach" to language teaching (p. 195).

Regarding the latter, the development of non-NESTs' language proficiency, Cullen (1994), for example, argues that, given a circumstance in which CLT has been widely used around the world, teacher training programs need to take non-NESTs' language demands into serious consideration. He introduces an in-service teacher training model, which integrates language elements with other components, especially methodology, by providing trainees with direct learning experiences as language learners. According to him, such a model is valuable because of its objective to meet teachers' needs and its practice-driven approach. In addition, Murdoch (1994) also introduces a curriculum revision of the teacher education program in Sri Lanka to develop teachers' English language proficiency levels. Among a total of 208 in- and pre-service non-NESTs participated in his study, many trainees viewed linguistic skills as the most important components in their professional expertise. Therefore, Murdoch suggests that teacher trainees' language proficiency should be the priority of the teacher-training curriculum, especially in the early stage of the program, to reduce their anxiety caused by the lack of language ability.

As can be seen, non-NESTs have faced various challenges in their profession such as perceived low self-confidence, concerns regarding applicability of their acquired knowledge, and lack of their voices in the professional community. To help them become successful ELT professionals, however, several teacher educators in the TESOL field introduce different approaches to L2 teacher education. In the Inner Circle, these approaches include a graduate seminar discussing non-NESTs' issues (Samimy and Brutt-Griffler, 1999), "the cross-curricular approach" (Kamhi-Stein, 2000), and "an introductory first semester course" for non-NESTs (Carrier, 2003). In the Expanding and Outer Circles, Cullen (1994) specifically suggests an approach integrating language elements across the curriculum. Other researchers discuss the importance of non-NESTs' double roles as mediators for their professional development.

Conclusion

The literature reviewed in this paper demonstrates that there has been recently a growing interest in the issues of non-NESTs such as the definitions of native and non-native speakers, non-NESTs' perceptions of their status and roles, and their professional development. In the first area, although the definition of a native speaker is highly debatable and problematic,

the underlying assumptions of existing pedagogical models in TESOL are primarily based on a native-speaker model. In terms of non-NESTs' status and roles, a body of literature explores their perception of their professional expertise in comparison to native teachers. Some scholars emphasize the differences in each type of professionals' teaching behavior mainly in relation to language competence and recognize non-NESTs' advantages and disadvantages as compared to NESTs. Other scholars, by contrast, consider such native/non-native dichotomy problematic because of the multidimensionality involved in their professions. Another body of the literature on non-native teachers' professional development examines their needs, challenges, and concerns, and further demonstrates several attempts made in the TESOL programs inside and outside the Inner Circle in order to meet non-NESTs' needs.

Thus, the existing literature on the three areas has provided us with great insights into the issues involved in non-NESTs. More research, however, needs to be conducted to further understand and handle various issues that they have faced. Based on the findings and discussions of the studies reviewed in this paper, the following future research questions can be suggested. First, instead of simply transferring the native speaker models to various teaching contexts, alternative pedagogical models need to be explored and field-tested. This research must be foremost, as the issue relates to the goals of English language learning and teaching both at the macro (e.g. national curriculum) and micro (e.g. school and classroom) levels in given contexts. Second, in the area of non-NESTs' status and roles, instead of dichotomizing ELT professionals based on native/non-native status, more research on what professional expertise is required to be successful ELT professionals in a given context needs to be studied. In so doing, the questions such as what the nature of English language learning as a subject is (Widdowson, 1994) and how non-NESTs can develop their unique roles as mediators must be explored. For non-NESTs professional development, more case studies in different social contexts need to be conducted to investigate their professional needs and concerns (Samimy and Brutt-Griffler, 1999). In addition, the question of what kind of trainings in the L2 teacher education programs will better develop non-NESTs' professional competence in the given contexts need to be explored. To do so, it is critical to examine prospective and currently working teachers' experiences of learning to teach in the contexts of L2 teacher education programs and schools. These studies will eventually help voice their concerns and needs related to their professions. Some scholars also point out that the studies in the field of L2 teacher education especially in the Expanding Circles are considerably scarce (Widdowson, 1997; Crandall, 2000). To develop effective L2 teacher education programs for non-NESTs, more EFL teachers' voices need to be incorporated into the L2 teacher education field. Finally, to develop effective L2 teacher education programs for non-NESTs both inside and outside the Inner Circle, studies examining the applicability of their learning in TESOL programs also need to be explored.

Nonstandard Language Use

A Bezuidenhout, University of South Carolina, Columbia, SC, USA

© 2006 Elsevier Ltd. All rights reserved.

To talk of *non*-standard language use presupposes that we understand what it is for a use of language to be *standard*. A standard use can be thought of either as a use that conforms to some standard (viz. to a linguistic rule or convention) or as a use that is the usual or most common one. So, a non-standard use is either one that flouts a linguistic convention or that is an uncommon or novel use. Various linguistic phenomena somehow marked as non-standard will be discussed and classified as belonging to one or another of these two categories of non-standard usage. A possible third sense of 'non-standard,' which is the opposite of Bach's (1995) notion of a standard*ized* use, also will be discussed. Although non-standardized uses may be *pragmatically marked* uses of expressions, they don't flout linguistic conventions and are not novel. Speech errors, such as cases in which a speaker says 'pig vat' instead of 'big fat,' also could be viewed as cases of non-standard language use, but will not be discussed in this article.

A conventional use, one conforming to a linguistic convention, is an agreed-upon use. The agreement needn't be an explicit one but simply a matter of members of a linguistic community conforming their use to that of other members of the community, so long as others do the same. Malapropisms are one sort of example of *non*-conventional use. Malapropisms are cases where a speaker (unintentionally) substitutes a word for another word, whose agreed-upon

education. New Haven, CT: Yale University Press. 82–88.

Nonstandard Language Use

A Bezuidenhout, University of South Carolina, Columbia, SC, USA

© 2006 Elsevier Ltd. All rights reserved.

To talk of *non*-standard language use presupposes that we understand what it is for a use of language to be *standard*. A standard use can be thought of either as a use that conforms to some standard (viz. to a linguistic rule or convention) or as a use that is the usual or most common one. So, a non-standard use is either one that flouts a linguistic convention or that is an uncommon or novel use. Various linguistic phenomena somehow marked as non-standard will be discussed and classified as belonging to one or another of these two categories of non-standard usage. A possible third sense of 'non-standard,' which is the opposite of Bach's (1995) notion of a standard*ized* use, also will be discussed. Although non-standardized uses may be *pragmatically marked* uses of expressions, they don't flout linguistic conventions and are not novel. Speech errors, such as cases in which a speaker says 'pig vat' instead of 'big fat,' also could be viewed as cases of non-standard language use, but will not be discussed in this article.

A conventional use, one conforming to a linguistic convention, is an agreed-upon use. The agreement needn't be an explicit one but simply a matter of members of a linguistic community conforming their use to that of other members of the community, so long as others do the same. Malapropisms are one sort of example of *non*-conventional use. Malapropisms are cases where a speaker (unintentionally) substitutes a word for another word, whose agreed-upon

meaning is different from what the speaker intends to convey. Usually the substitution is based on some sort of sound similarity between the 'correct' and 'incorrect' usage.

In his play *The Rivals*, Richard Sheridan has a lot of fun at the expense of his character Mrs. Malaprop. For example, Mrs. Malaprop exclaims to Sir Anthony Absolute, 'you surely speak laconically!,' meaning to surmise that Sir Anthony is speaking ironically. A little later she hopes that Sir Anthony will regard her niece, Lydia Languish, 'as an object not altogether illegible,' meaning that she hopes her niece will not be regarded as someone ineligible for a match with Sir Anthony's son.

Such malapropisms are not confined to fiction. For example, in some experimental work on referential communication reported by Brown (1995), a participant in a map-reading task referred to an electric pylon as a colon. Another example occurred on the June 16, 2004, broadcast of the Tavis Smiley Show on National Public Radio. One of Smiley's guests praised him by saying, 'You have spoken up so unanimously for black people.' The concept of unanimity only makes sense when one is talking about a group of people, and Smiley is a single individual. However, what the guest was thinking is that whenever Smiley speaks up he speaks up for black people. So, if one thinks of Smiley and his past selves as a group, one can think of them as speaking with one voice and hence as unanimous. This last example shows that malapropisms are not always based on *sound* similarities but can arise from quite complicated cognitive comparisons (e.g., Smiley and his past selves are like a group of individuals).

Malapropisms are extreme examples of misuse, and rather idiosyncratic. There are other examples of 'misuse' that are more widespread among members of a linguistic community. For example, many people use the sentence, 'Hopefully, Bush will be defeated' to express their hope that Bush will be defeated, not the thought that the defeating of Bush will be performed with hope. Or again, many people say things such as, 'Me and him are going to the movies' or 'I could care less' or 'Everyone will be bringing their spouses' instead of 'He and I are going to the movies' or 'I couldn't care less' or 'Everyone will be bringing his or her spouse.'

Given how widespread these latter 'misuses' are, one might argue that, rather than being misuses of English, they are acceptable uses within some 'non-standard' dialects of English. Calling these dialectical varieties 'non-standard' is rather contentious. There are some language purists who argue that only 'standard' English is acceptable usage. However, as Chomsky (2000) points out, calling some varieties of English 'standard' and regarding them as normative for English usage generally has nothing to do with the linguistic properties of these language varieties, but is purely a matter of power politics. The dialect of the ruling group is inevitably regarded as the norm for correct speech. Everyone has heard the old saw about a language being a dialect with an army and a navy. But as Chomsky remarks: "To say that one variety of English is 'right' and another 'wrong' makes as much sense as saying that Spanish is right and English is wrong" (2000: 71).

According to the second sense of 'non-standard' articulated above, non-standard uses are novel or 'nonce,' i.e., one-off, uses. The largest class of uses that have been thought of as 'nonce' are the uses of sentences to convey Gricean *particularized* conversational implicatures. For instance, a mother asks her teenage son to tidy his room and he replies: 'I have to beat this boss real quick.' The son is explicitly talking about what he has to do in the video game he's playing but is implicitly refusing to clean his room right then. In this sense of 'nonce' meaning, the novel meaning is something that is merely *indirectly* or *implicitly* conveyed. Such nonce meanings are conveyed because the hearer understands the speaker to have explicitly said one thing but to have meant something else (either in addition or instead). Thus, implicatures are not nonce meanings *for expressions*. Rather, they are novel meanings conveyed *by* the use of expressions that are understood to have their conventional meanings.

Metaphorical, ironic, metonymic, and other such 'non-literal' uses of expressions have also been thought of as nonce uses. For example, 'The soldiers butchered the villagers' can be used metaphorically to express the fact that the soldiers killed the villagers in a particularly inhumane way. 'You're a fine friend' can be used ironically to express the fact that the hearer has done something unfriendly. 'The ham sandwich is getting restless' can be used metonymically to express the fact that the orderer of the ham sandwich is getting restless. Many philosophers analyze such uses in terms of Gricean particularized conversational implicatures. The speaker says one thing but indirectly conveys something else. Inasmuch as such uses are analyzed in Gricean terms, these again would not be cases in which *expressions* are given novel meanings. Rather, *by* using expressions with their conventional meanings, speakers *indirectly* express novel meanings.

(Of course, the examples of metaphor, irony, and metonymy given above are very hackneyed, and in this sense are not 'novel.' For example, the 'butcher' metaphor has become a 'dead' metaphor. Many dictionaries of English usage now list 'to kill in a brutal

manner' as one of the meanings of 'to butcher.' Other, 'fresher,' examples could have been given, but these would have required more context setting.)

Not everyone would agree that cases of metaphor and metonymy are correctly analyzed in Gricean terms. An alternative 'contextualist' view denies that we interpret the entire sentence literally and only then (because of a violation of some Gricean maxim, such as the maxim of quality) derive an implicated metaphorical meaning. For example, consider the following

(1) Dickens is easy to read.

(2) The appendectomy is on top of the cabinet.

(3) The stinkbug has left the room.

In (1), which is an example of a producer-for-product metonymy, 'Dickens' is used to refer to the novels that Dickens wrote. In (2), one can imagine a context in which 'the appendectomy' is used to refer to the file of the patient who is scheduled for an appendectomy. And in (3), 'the stinkbug' can be used metaphorically to refer to a person whose personal hygiene leaves much to be desired. According to the contextualist, local pragmatic processes operate on the referring terms ('Dickens,' 'the appendectomy,' 'the stinkbug') to yield pragmatically determined contents. These become a part of the propositional contents that are directly expressed by sentences (1)–(3) in their conversational contexts. For example, the speaker of (2) doesn't say falsely that a medical procedure is on the cabinet and thereby indirectly convey the proposition that the file of a patient scheduled for an appendectomy is on the cabinet. Rather, the latter proposition is directly expressed. See Carston (1997) and Bezuidenhout (2001) for a defense of the contextualist view of metaphor.

If this view is correct, there is a sense in which the expressions 'Dickens,' 'the appendectomy,' etc. are given novel meanings in different contexts. These novel meanings are not merely indirectly conveyed *by* literally saying something else. Note, this view is *not* committed to a 'Humpty Dumpty' theory of meaning, according to which expressions can mean whatever their users intend them to mean. (In *Through the Looking-Glass*, Humpty Dumpty says to Alice, 'There's glory for you' and claims to mean 'There's a nice knockdown argument for you.') According to the contextualist view, the novel contextual meanings of expressions are pragmatic developments of semantically encoded meanings. The local pragmatic processes that determine contextual meanings are thus not completely unconstrained. Speakers cannot convey novel meanings that are completely unrelated to conventionally encoded meanings. (For a more radical view, see Donnellan [1968] and Davidson [1986]. They argue that, in appropriate contexts, 'glory' *can* mean *a nice knockdown argument*.)

Another class of uses that have been called 'nonce' are ones in which speakers coin new words. Attested examples are as follows, the first two given by Clark (1992: 315–316), the third by Higginbotham (2002: 577):

(4) He's being grand juried for possible conflict in real estate loans.

(5) Today I'm going gallerying.

(6) I've hard-drived the diskette.

These novel uses are similar to ones that have already entered common usage, such as 'He docked the boat' or 'The librarian shelved the books.' These uses all obey a productive rule, in which a noun is turned into a verb by the addition of a verbal particle ('–ed' to signal past tense, '–ing' to signal an ongoing or incomplete action). The novel words are coined because there is no readily available, short expression already in common use that quite covers the speaker's intended meaning.

In some cases, people invent new words when there are already perfectly good words in common usage that mean exactly what the speaker intends. For example, on the June 16, 2004, edition of the *Tavis Smiley Show* on NPR, one of Smiley's guests said: 'You have to conversate and talk to your child on a man to man level.' Presumably what was meant was that one should *converse* with one's child. What is already a verb, 'to converse,' is subjected to a morphological rule for verb formation, by the addition of the suffix '–ate,' perhaps on analogy with the verb 'to orientate,' which is frequently used instead of the plain 'to orient' (this latter being the norm in standard American English, although not in standard British English, which favors 'to orientate').

A third sense of 'standard use' should be mentioned. It corresponds to what Bach (1995) calls a *standardized* use, which he distinguishes from a conventional use. One reason that Bach appeals to his notion of standardized use is to counter attempts by relevance theorists such as Carston (1995) to reconstrue Gricean *generalized* conversational implicatures as part of what is directly expressed. Consider, for example, the Gricean treatment of scalar terms, such as numerals. On this view, 'Grice has three teeth' literally says that Grice has *at least* three teeth, but it conversationally implicates in a generalized way that Grice has *at most* three teeth. These two propositions together entail that Grice has *exactly* three

teeth. Carston's alternative view is that 'three teeth' is semantically underspecified. When used in an appropriate context, it can be specified in such a way that what is said (i.e., what is explicitly conveyed) in that context by 'Grice has three teeth' is that *Grice has exactly three teeth*.

Bach offers a third alternative. On this view, 'three teeth' has a standardized use to convey *exactly three teeth*. A standardized use is something like a default use. It is a default in the sense that it has become a regular practice – perhaps a mental habit – for members of the linguistic community to use the word(s) in question in a certain way, given that circumstances are normal. Only if circumstances are somehow unusual will a different interpretation be called for. Bach denies that the standardized meaning is explicitly conveyed. It is implicitly conveyed (he calls it an 'impliciture'), but because it is conveyed by default in normal circumstances, it gives the illusion of being directly conveyed. The inference that is needed to derive this standardized interpretation has become compressed by precedent. Hence, hearers are not aware of having made any inference. A similar view, according to which generalized implicatures are default inferences, has been defended by Levinson (2000).

The details of Bach's views are not important here. The main point is to introduce a third sense of 'non-standard use.' It corresponds to a *non*-standardized use in Bach's sense. A non-standardized use is one that is called for when circumstances are somehow not 'normal' and hence the default meaning must be overridden. For instance, suppose Grice has a large collection of shark teeth and you need exactly three shark teeth for an artwork you are creating. Believing that Grice might be willing to give up some of his shark teeth for you I say 'Grice has three teeth.' Arguably what is conveyed here is that Grice has at least three teeth, not that he has exactly three. Now, according to Griceans such as Bach and Levinson, the conventionally encoded meaning of 'three teeth' is *at least three teeth*. In other words, when circumstances are *not* normal and the default meaning is overridden, the meaning that is conveyed is the literally encoded meaning. So the non-standardized use in this case is the conventional one (i.e., it is a standard use in the first sense articulated above).

In the example given in the previous paragraph, pragmatic context indicated that a non-default understanding of 'three teeth' was called for. Sometimes, however, the linguistic expression itself signals whether it is to be given a default or non-default reading. There are pragmatically marked and unmarked ways of saying things. Unmarked ways of saying things call for default interpretations. Marked ways of saying things call for non-default interpretations. For example, there is a difference between saying 'The policeman stopped the car' and 'The policeman brought the car to a stop.' The former suggests that the stopping was the normal sort of stopping, whereas the latter suggests that the policeman did something unusual to halt the car. But although non-standardized uses may be *pragmatically marked* uses of expressions, they don't flout linguistic conventions and they are not novel uses, or at least no more novel than their unmarked alternatives. Both 'The policeman stopped the car' and 'The policeman brought the car to a stop' will call for quite a lot of pragmatic inferencing to understand what the speaker said.

Nonverbal Communication

M Anderson, Purdue University, West Lafayette, IN, USA

Framing 'Nonverbal' and 'Communication'

Empirical researchers in the field of nonverbal communication must operationally define both 'nonverbal' and 'communication' to suit their investigations (Farnell, 2004). This is difficult because both notions carry extraordinarily wide connotations (cf. Sebeok *et al.*, 1964).

'Nonverbal' suggests a relationship with 'verbal,' that term narrowly referring to human spoken language, or speech. If that relationship with the 'verbal' is obligate, 'nonverbal' would be limited to communication accompanying, complementing, or substituting for speech, termed the paralinguistic. If, on the other hand, the relationship with the 'verbal' is instead one of contrast, 'nonverbal' would potentially include any and all extralinguistic communication.

Then, most inclusively, communication (in terms of transmission of information, matter, and/or energy) extends beyond the realm of humans, certainly when it involves sentient organisms; all such nonhuman communication is perforce 'nonverbal.' Ultimately, beyond 'nonverbal communication,' webs of 'communication' connect everything from planets to living things to molecules, in orbits of relations of significance and exchange. However, the typical frame for 'nonverbal communication' will be restricted here to the human.

Situating Nonverbal Communication Studies within Semiotics

The semiotic analysis of nonverbal communication only partially parallels the semiotic analysis of verbal communication (Key, 1980). Verbal communication draws on human language (modeled as deep structure), realized vocally as speech and its nonvocal derivatives such as writing (both modeled as surface phenomena), all studied within linguistics. Semiotics as a whole subsumes linguistics together with the diverse disciplinary and metadisciplinary approaches to the understanding of communication within culture and nature as a whole.

Specifically, semiotics studies signs and the behavior of signs in space and through time, signs being anything carrying significance in a system. Significance boils down to meaning-making, that is, potential communication, irrespective of the agents, patients, subjects, objects, or media of the process. We tend to think first of humans as communicators, and moreover of them communicating in the medium of human language. Human verbal language may be carried by sound, as in speech, or visually, as through writing. Nonverbal communication associated with human verbal behavior ranges from aspects of vocalization accompanying speech (intonation, stress, pitch, rhythm, etc.) to nonvocal bodily gestures, movement, and interpersonal spatial positioning, accessed by vision and other senses (Birdwhistell, 1952; Efron, [1941] 1972; Kendon, 1997; Wenzel, 1968).

Webs of Verbal, Nonverbal, Vocal, and Nonvocal Communication

Nonverbal communication without obligatory ties to language is by far the most diverse category, and may be vocal, involving sounds originating in the vocal tract, or nonvocal. Nonvocal signs in turn may draw on sound production and interpretation, as in whistles and clapping, or may involve any other sense modality – such as vision, olfaction, taste, and touch, with vision paramount, whether through gesture, dress styles, or architecture.

Another foundational distinction made in nonverbal communication centers on context, especially whether face-to-face, more generally interpersonal, or between more remote actors (Goffman, 1963). Contemporary media have introduced many innovations for nonverbal communication. Cell-phone use is verbal, leading to some ordinary nonverbal signs accompanying speech being masked by the medium while others are exaggerated. Emailing represents the verbal both nonverbally and nonvocally, in writing; yet further nonvocal and vocal nonverbal expression seeps in through emoticons and yet-to-be standardized strings of icons, indexes, and symbols.

Finally, sign languages for the deaf, such as American Sign Language (ASL), are quintessentially both nonverbal and nonvocal communication (Armstrong *et al.,* 1995). These constitute, however, genuine languages with full syntactic and productive properties, which cannot be said for so-called body language (Eibl-Eibesfeldt, [1967] 1975) or for the communication systems of other animals (Rauch and Carr, 1980).

Semiotic research on nonverbal communication by linguists, anthropologists, cognitive psychologists, and others ranges from the experimental (often quantitative, considering individual, internal, and

microunits of analysis) to the naturalistic (usually qualitative, assessing social, relational, embodied, and emergent units of analysis) (Schere and Ekman, 1982; Poyatos, 1992).

The Primary Media of Sound (Oral–Aural) and Sight (Vision)

In referring to nonverbal communication, the first frame of reference will be that contrast with human verbal language. In connection with language and speaking, nonverbal communication itself may be vocal or nonvocal, depending on the activation of the vocal chords or other sound-shaping apparati of the mouth and vocal tract, keeping the coding and decoding within the oral-aural realm as spoken language itself. Examples of such nonverbal communication include intonation, stress, pitch, and rhythm. These elements of sound coupled with tempo vitally contribute to the verbal message, whether emphasizing that message or calling the message into question. While the symbols of the International Phonetic Alphabet support the transcription of the sound units of verbal language, nonverbal coexpression can only be more provisionally transcribed in notational systems inclined to be iconic and indexical, rather than symbolic.

Spatially located visual elements also contribute to any verbal message. Of great significance in speech are those nonvocal facial (Ekman, 1972) and bodily (mostly hands and arms) gestures (Bremmer and Roodenburg, 1992) accompanying articulation – these sometimes affecting the voice itself. For instance, the hearer can detect when a speaker is smiling, even on the telephone. Other gestures, say, a shrug, can shape if not negate the verbal message itself.

Still another realm of semiotic research centers on nonverbal vocal utterances not in conjunction with speech, studied as extralinguistics. Some extralinguistic phenomena such as laughing and crying may appear to be species-specific, but in fact these are for the most part shaped by culture, particularly if the pragmatic context is considered. The sounds generated by laughing, crying, screaming, sighing, and other nonverbal vocal utterances vary by individual and culture, and the culture further determines when, where, how, and why such utterances occur. A sigh, for instance, carries meaning, regardless of whether it occurs with speech or in other contexts; it's worth noting that the sigh does not carry vocal-chord sound although it is generated by the vocal tract.

Paralinguistic (nonlinguistic sounds, such as sighing, hissing, and hesitations; and marked linguistic sounds, such as pitch and interruptions) and extralinguistic (and, by extension, 'nonverbal,' such as bodily signs) communication may also rely on sound and sight, as well as on other sense modalities such as smell, taste, and touch.

A much larger category of bodily communication, being neither verbal nor vocal, stands alone without linguistic accompaniment, although some may flourish in a setting including linguistic communication. The body itself communicates particularly through the face, and through all gestures, all stances, and all other behavior, especially that involving movement (Birdwhistell, 1952) and distance (Hall, 1959) as well. The body's sign-generating potential is magnified through culture, when dress, adornment, and setting can trump the visual accessibility of the body. However, in any case, olfactory signs (smell) and haptic signs (tactile touch) shape communication when communicators are in each other's presence, and one cannot discount the occasional role of gustatory signs (taste).

The face, the privileged location of most of the sense receptors (ears, eyes, nose, tongue, and very sensitive skin), also continuously expresses and nonconsciously exudes meaningful gestures (Ekman, 1972). The face communicates through intended and unintended signs, isolated by Ekman as action units, and either category of signs may be recognized and interpreted, *or* misinterpreted, *or* ignored by others. The pout is hard to miss and is readily evaluated, but the dilation of the pupil of the eyes may not be consciously noted by either actor or observer. Furthermore, the individuals aware of such and other communication will seldom be limited to the intended or known audience.

The unintended signs leaking, as it were, from the face, comprise those macroscopic expressions discernible by conspecifics (and sometimes other coevolved creatures), as well as very short and slight muscle movements only subliminally recognized by the observer, although with training individuals can both produce and detect these signs. Pupil dilation, indicating peaked interest, lies on the threshold of such signs that untrained persons can detect. Eyebrow flashing, indicating surprise, is more subtle.

Folding in Infra-individual Emotion and Extra-individual Culture

Much nonverbal communication will be suffused with and will project subjective feelings subject to underinterpretation and overinterpretation by others. All humans share a finite number of basic emotions compared with the plethora of named conditions found in any language and culture (Russell *et al.*,

2003). By inference, and anthropomorphically, humans interpret certain of these emotional states in other animals as well (Darwin, [1872] 1965; Eibl-Eibesfeldt, [1967] 1975). Not surprisingly, emotions motivate much of communication in any medium and in all venues.

Nonverbal communication among humans also involves material and nonmaterial culture. We construct and are surrounded by disembodied signs in advertising, art, architecture, film, furniture, music, spectator sports, theater, and zoological gardens. A semiotic perspective enables the articulation of the individual agent as sign-producer and -interpreter, with the ephemeral emergent properties of emotion and with the longer traditions of history-laden spectacles and artifacts.

Nonverbal Predication

L Stassen, University of Nijmegen, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Definition of the Domain

In the tradition of Western linguistics, the domain of predication is usually considered to cover four semantic subtypes. First, there are predicates that express an event (an action, state, or process). Since such predicates are prototypically encoded by verbs, event predication can typically be described as verbal predication. An English example of a verbal predication is the sentence given in Example (1):

(1) Mary sing-s.

In addition, and often in contrast, to verbal predication, the predicational domain also contains predications in which the predicate refers to a property (adjectival predication), to a class (nominal predication), or to a location (adverbial predication). English examples of these three predicational categories are seen in the following sentences:

(2) Mary is beautiful.
Mary is a teacher.
Mary is in the garden.

As can be seen, these sentences contrast with the verbal predication in Example (1) in terms of their formal encoding strategies. Whereas, in English, event predicates can be marked by bound morphology for tense and subject agreement, this encoding option is not available for the various predicate categories in Example (2). Thus, sentences such as those in Example (3) are ungrammatical in English:

(3) *Mary beautiful-s.
*Mary teacher-s.
*Mary in the garden-s.

We can conclude, then, that for English, there are formal reasons to make a distinction between verbal predication (which is typically used to express events) and nonverbal predication (which is used to express the other three predicate categories). The situation encountered in English is an instance of a major pattern in the encoding of the domain of predication. It is, however, by no means the only way in which the domain of predication can be encoded; as will be seen in the following discussions, neither the uniformity of the nonverbal predicational strategy nor the distribution of verbal and nonverbal encoding over the four predicational strategies, as found in English, is a universal feature of human language.

Criteria for Verbal and Nonverbal Predicate Encoding

In order to be able to set up a typology of the ways in which the domain predication is encoded cross-linguistically, we need a set of language-independent criteria to decide whether a given predicate encoding must be rated as verbal or nonverbal. Such a set of criteria was developed by Wetzer (1996) and Stassen (1997). The first of these is the agreement criterion:

(4) The Agreement Criterion
If a language has (person/number/gender) agreement on predicative verbs, then other predicate categories in that language will be rated as verbal if they show this agreement marking as well. If they do not, they will be rated as nonverbal.

In order to simplify, the discussion here is restricted to examples of the encoding of property predicates (adjectival predicates). As is demonstrated by the first sentence in Example (2), **Mary is beautiful*, the application of the agreement criterion to English enables us to decide that English has nonverbal adjectival predicates. In contrast, a language such as Bororo (Ge-Bororo) must be said to have verbally encoded adjectival predicates, as is demonstrated by the Bororo sentences in Examples (5a) and (5b) (Crowell, 1979: 50):

(5a) i-mago-re
1SG-speak-NEUTRAL
'I speak/spoke.'
(5b) i-kure-re
1SG-tall-NEUTRAL
'I am/was tall.'

A second criterion that – alone, or in alignment with the agreement criterion – can decide on verbal or nonverbal status of predicate categories is the auxiliary criterion:

(6) The Auxiliary Criterion
If a predicate category is marked by the presence of a supportive item (an auxiliary), then its encoding must be rated as nonverbal.

Application of this criterion yields, in addition to the agreement criterion, the conclusion that English predicative adjectives are nonverbal, since they need the auxiliary item *be*. A case in which the copula criterion is the sole decisive factor is presented by Modern Irish (Gaelic, Irish), as shown in Examples (7a) and (7b) for Modern Irish (Indo–European, Celtic; see Greene

(1966: 46)). In this language, predicative verbs do not show any agreement marking, so that the agreement criterion is not applicable here. Nonetheless, we can decide on nonverbal status for Irish predicative adjectives, by virtue of the auxiliary criterion (COP, copula):

(7a) téann Sean
go.PAST S.
'Sean went.'

(7b) is breoite é
COP.PRES. ill he
'He is ill.'

For languages that lack both auxiliaries and agreement marking on verbs, the two criteria presented in Examples (7a) and (7b) are not applicable. For this case, we therefore need an additional third criterion, the negation criterion.

(8) The Negation Criterion
If a predicate category has a negation that differs from the negation of predicative verbs, then the encoding of that predicate category must be rated as nonverbal.

The application of this criterion can be illustrated by the facts in Gumbainggir (Kumbainggar; Australian, Pama-Nyungan) and Tagalog (Austronesian, Philippine). Both languages lack auxiliaries and agreement on verbs. However, according to the source (Eades, 1979: 332), Gumbainggir has different negation strategies for predicate verbs and adjectives, whereas the negation strategy in Tagalog is the same for the two predicate categories (Examples (9a) and (9b); see Schachter and Otanes (1972: 518)). Hence, we decide that predicative adjectives are nonverbal in Gumbainggir, whereas they are verbal in Tagalog (TOP, topic):

(9a) hindi dumating ang bus
NEG come TOP bus
'The bus did not come.'

(9b) hindi mura ang karne
NEG cheap TOP meat
'The meat is not cheap.'

The Encoding of Adjectival Predicates

By applying the set of three criteria, it is possible to decide on the verbal or nonverbal status of any case of predicate encoding in a language-independent fashion. As a result, we are able to determine the stratification of the domain of predication (i.e., the distribution of verbal and nonverbal encoding strategies over the four predicate categories) for any language. Typological investigations into the stratification options for the domain of predication were conducted by Hengeveld (1992) on a sample of 50 languages and by Stassen (1997) on a sample of 410 languages. It turns out that there are several different parameters in the typology of predicational encoding, and that these parameters interact with one another in sometimes fairly subtle and complicated ways. Nonetheless, some general crosslinguistic trends can be stated with some degree of confidence.

First of all, the research reveals the following general crosslinguistic fact of predication encoding:

(10) No language employs more than three different encoding strategies for the domain of predication.

In other words, no natural language employs a different encoding strategy for all four predicational categories. The reason for this restriction on logically possible stratifications of the predicational domain lies in the encoding behavior of adjectival (i.e., property-concept) predicates. It can be established that the following crosslinguistic generalization holds:

(11) Property-concept predicates never have an encoding strategy that is exclusive to them. That is, their encoding is always 'taken over' by a (verbal or nonverbal) encoding strategy that is employed for the encoding of one or more of the other predicate categories.

The 'dependence' of adjectival predicates on the encoding of other predicate categories is usually explained in terms of the notion of 'time stability' (see, among others, Givón (1984)). On the scale of time stability (which orders predicates in terms of their 'permanency,' or 'resistance to change over time'), property concepts take a middle position between (very time-unstable) event predicates and (very time-stable) class predicates. In this way, property predicates constitute a 'battleground' (to use the terminology coined in Stassen (1997)) for the encoding strategies of verbal and nominal predicates, and they are taken over by either the verbal strategy or a nonverbal (usually, the nominal) encoding strategy. This, of course, raises the question of whether, in a given language, the outcome of this battle can be predicted. Wetzer (1996) and Stassen (1997) identified a parameter that appears to have remarkable predictive power in this respect. This parameter, called the 'tensedness parameter,' can be defined as follows (Stassen, 1997: 350–351):

(12) If a language has a grammatical category of tense that
(a) is morphologically bound on verbs and
(b) minimally involves a distinction between past and nonpast time reference, then that language is tensed. In all other cases, a language is nontensed.

The relation between the tensedness parameter and the encoding behavior of adjectival predicates can be stated in the following universals (Stassen, 1997: 357):

(13) The Tensedness Universals of Predicate Adjective Encoding
  (a) If a language is tensed, its predicate adjectives will be encoded nonverbally.
    If a language has nonverbally encoded adjectival predicates, it will be tensed.
  (b) If a language is nontensed, its predicate adjectives will be encoded verbally.
    If a language has verbally encoded predicate adjectives, it will be nontensed.

Both Wetzer (1996) and Stassen (1997) demonstrated the validity of these universals: counterexamples to either condition (a) or (b) in Statement (13) can be judged as 'incidental.' By way of an explanation of the correlation between tensedness and adjectival predicate encoding, Stassen (1997, 571–574) suggested the operation of principles that have to do with the general notion of iconicity.

Major Types of Predicate Encoding

The encoding behavior of predicate adjectives can be seen as a first constraining factor on the options that languages have in the stratification of the domain of predicate encoding. Most of the logical possibilities that remain after this restriction has been taken into account turn out to be attestable in at least some languages. There are, however, four stratification types that are clearly more prominent than the others, in that they occur more frequently and are usually less area determined.

The first of these stratification types can be described as 'uniformly verbal.' That is, under this type, all four predicate categories receive a verbal encoding. An example of a language in which this stratification type can be attested is Mundari (Austro–Asiatic, Munda), as shown in the following sentences (Hoffmann, 1903: 16; Langendoen, 1967: 85, 90; Bhat, 1991: 734) (INDIC, indicative; PRED, predicative):

(14a) sen-a-ing
go-INDIC–1SG
'I am going/will go.'

(14b) hodo-ko mara-a-ko
man-PL tall-PRED–3PL
'The men are tall.'

(14c) hodo-ko en-taq-re-ko-a
man-PL that-place-in–3PL-PRED
'The men are there.'

(14d) ne dasa horo-a-e
this servant Munda-INDIC–3SG
'This servant is a Munda.'

Second, we find a stratification type that can be described as 'almost uniformly verbal.' Under this type, all predicate categories receive verbal encoding, with the exception of locational (adverbial) predicates. The stratification can be illustrated by the facts of the Menomini (Algonquian) language (Bloomfield, 1962: 42, 51, 275) (ANIM, animate; INTRANS, intransitive):

(15a) mɛqsi-w
big-3SG.ANIM.INTRANS
'He is big.'

(15b) pi·-w
come-3SG.ANIM.INTRANS
'He comes/came.'

(15c) awɛ·tok-ɛw
spirit–3SG.ANIM.INTRANS
'He is a spirit.'

(15d) as i·-w
there/at.home be-3SG.ANIM.INTRANS
'He is at home.'

Third, a frequently encountered stratification type can be described as 'split verbal–nonverbal.' Under this type, event predicates and property-concept predicates (i.e., verbs and adjectives) are encoded verbally. Class (nominal) predicates and locational (adverbial) predicates each have their own, separate, nonverbal encoding strategy. A language that exhibits this stratification pattern is Mandarin Chinese (Sino–Tibetan, Sinitic); as can be seen in the following examples (Comrie, 1976: 20; Li and Thompson, 1981: 148, 365, 410), the language uses different, and noninterchangeable, auxiliaries for nominal and adverbial predicate encoding:

(16a) tā gao
3SG tall
'He/she is tall.'

(16b) Z~ngsh~n shì yi-ge hùshì
Z. COP one-CLASS nurse
'Zangshan is/was a nurse.'

(16c) Lǐsì zài hǎi-bi~n
L. be.at ocean-side
'Lisi is by the ocean.'

(16d) t~ pǎo
3SG run
'He/she runs/ran/will run.'

Fourth, and finally, we encounter a major stratification pattern that can be characterized as 'maximally nonverbal.' In this type, only event predicates are encoded by the verbal strategy. In the typical case, the other three predicate categories are encoded by a uniform nonverbal strategy, which can be employed indiscriminately for predicate adjectives, predicate nominals, and predicate adverbials alike. English,

with its nonverbal auxiliary *be*, is an example of this stratification pattern.

Schematically, then, the four major patterns of predicate encoding can be represented as follows (where V, N, and L stand for verbal, nominal, and locational encoding, respectively):

(17) Major patterns of predicate encoding:

Pattern:	I	II	III	V
Event:	V	V	V	V
Property:	V	V	V	N/L
Class:	V	V	N	N/L
Location:	V	L	L	N/L

An interesting question is why some languages should keep their nominal and locational strategies separate, whereas others have integrated them into one uniform nonverbal strategy. Stassen (1997: 584) suggested that this distinction is dependent on the encoding behavior of predicate adjectives in the language: if predicate adjectives are encoded verbally, nominal and locational encoding will be separate, whereas languages with nonverbal predicate adjectives tend to have an integrated uniform nonverbal strategy. Apparently, predicate adjectives serve as some sort of 'bridge' between nominal and locational predicates, and if this 'bridge' is 'closed down' through verbal encoding of predicate adjectives, the integration of the nominal and locational encoding strategies is prevented. A full model of the domain of predicate encoding can be found in Stassen (1997, Chap. 14).

Noreen, Adolf Gotthard (1854–1925)

A Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Adolf Gotthard Noreen was one of a group of highly productive Scandinavian linguists of the late 19th and early 20th centuries who in their work represent the transition from the 'old' philology to the 'new,' from concern with older varieties of modern languages and their historical development to concern with the contemporary languages and variation within them. Other linguists who also exemplify this transition are Noreen's fellow Swede Johan August Lundell, the Dane Otto Jespersen, and the Norwegian Johan Storm. Their approach had much in common with that of the British linguist Henry Sweet, and there is good reason to speak of an Anglo-Scandinavian School straddling the turn from typically 19th-century historical linguistics to more typically 20th-century descriptive approaches.

with its nonverbal auxiliary *be*, is an example of this stratification pattern.

Schematically, then, the four major patterns of predicate encoding can be represented as follows (where V, N, and L stand for verbal, nominal, and locational encoding, respectively):

(17) Major patterns of predicate encoding:

Pattern:	I	II	III	V
Event:	V	V	V	V
Property:	V	V	V	N/L
Class:	V	V	N	N/L
Location:	V	L	L	N/L

An interesting question is why some languages should keep their nominal and locational strategies separate, whereas others have integrated them into one uniform nonverbal strategy. Stassen (1997: 584) suggested that this distinction is dependent on the encoding behavior of predicate adjectives in the language: if predicate adjectives are encoded verbally, nominal and locational encoding will be separate, whereas languages with nonverbal predicate adjectives tend to have an integrated uniform nonverbal strategy. Apparently, predicate adjectives serve as some sort of 'bridge' between nominal and locational predicates, and if this 'bridge' is 'closed down' through verbal encoding of predicate adjectives, the integration of the nominal and locational encoding strategies is prevented. A full model of the domain of predicate encoding can be found in Stassen (1997, Chap. 14).

Noreen, Adolf Gotthard (1854–1925)

A R Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Adolf Gotthard Noreen was one of a group of highly productive Scandinavian linguists of the late 19th and early 20th centuries who in their work represent the transition from the 'old' philology to the 'new,' from concern with older varieties of modern languages and their historical development to concern with the contemporary languages and variation within them. Other linguists who also exemplify this transition are Noreen's fellow Swede Johan August Lundell, the Dane Otto Jespersen, and the Norwegian Johan Storm. Their approach had much in common with that of the British linguist Henry Sweet, and there is good reason to speak of an Anglo-Scandinavian School straddling the turn from typically 19th-century historical linguistics to more typically 20th-century descriptive approaches.

Noreen studied in Uppsala, which would become his home and place of work throughout his life. He eventually became a professor of Scandinavian languages, but he spent 1879 in Leipzig, where he studied Lithuanian with August Leskien; this solid grounding in Neogrammarian ideas and principles confirmed his commitment to historical language work. He produced a range of textbooks in Germanic philology, including the much-admired *Altisländische und Altnorwegische Grammatik (Laut- und Flexionslehre)* in 1884, which entered a fifth edition as late as 1970, and the *Geschichte der nordischen Sprachen besonders in altnordischer Zeit* of 1889–1891. Significant among these philological handbooks is also the substantial *Altschwedische Grammatik mit Einschluss des Altgutnischen*, the first such work, which appeared in complete form in 1904. It is noteworthy that as late as the early 20th century it was still felt to be good practice to publish serious linguistic studies in German and in Germany.

Noreen's most original contributions lay however with his descriptive rather than his historical work. His doctoral dissertation of 1878 was a study of the sound system of his home dialect of Fryksdal, which, in keeping with the dominant approach to dialect study in late 19th-century Scandinavia, was based on the most recent phonetic principles. He also made significant contributions to the study of Swedish place names.

Scandinavian linguists have never been afraid to come down from the academy and enter debates on practical issues like spelling reform, and Noreen was no exception, but his major work, despite its homely title, *Vårt språk* (Our Language), was a monolithic and scholarly description of the Swedish language. The first volume was published in 1903, and the work remained incomplete at the time of Noreen's death, having covered the history of the language, phonology, meaning, and inflectional morphology. This seven-volume detailed study takes the Swedish language in its historical entirety, and is a classic of the early 20th-century large-scale single-authored grammar genre.

Norfolk Island: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Of volcanic origin, Norfolk Island is located in the South Pacific Ocean, east of Australia, of which it is now a territory. Discovered by Captain Cook in 1774, it was claimed by him for Great Britain and named in honor of the Duchess of Norfolk. Cook sailed on, and the island was to remain uninhabited for a further 14 years. The period between 1788 and 1814 saw the first British penal colony on Norfolk Island; the second colony, the most brutal ever established by Britain, lasted from 1825 to 1855. In 1856, the island received those who call it home to this day: the Pitcairners, descendants of the *Bounty* mutineers. The descendants of the *Bounty* and their Tahitian wives brought their own language with them when they migrated to Norfolk Island in 1856 from Pitcairn Island. Norfolk (Pitcairn-Norfolk) is a unique mixture of 18th-century English and ancient Tahitian. English is the official language of Norfolk Island; however, the 1841 islanders (July 2004) use Norfolk on a regular basis to communicate. A slightly different variety than that diffused in Pitcairn, Norfolk is an in-group language used to assist in the preservation of identity. People speak Standard British English as a mother tongue; Norfolk is a second language only.

Normativity

S Gross, University of Pennsylvania, Philadelphia, PA, USA

© 2006 Elsevier Ltd. All rights reserved.

Normative claims concern the ways things should be. Nonnormative (or descriptive) claims concern how things are, which can diverge from how they should be. 'No one should speed' is a normative claim; 'they are speeding' is not. Neither is '85% of drivers speed,' even if it describes how things in fact normally are. Statistical norms must be distinguished from norms or standards for how things ought to be.

In exploring the relevance of normativity to language, it is useful to bear in mind that normative claims fall into various kinds and can possess a range of further features. Consider the following examples:

1. Sheets should be clean.
2. Friends should not spread gossip.
3. Smoking is permitted.
4. If you believe some claim, you shouldn't believe its negation.
5. Only goalkeepers may touch the ball with their hands.
6. Goalkeepers should avoid straying from their goal.
7. Pedestrians may cross only at the crosswalk.
8. You shouldn't wear blue slacks with a brown jacket.
9. If you want to improve, you should practice more.

These examples illustrate a variety of features of normativity. Normative claims may state, not only how things should be (1), but also how they should *not* be (2), as well as how they are allowed though not necessarily required to be (3). The subject of norms can include agents (2), actions (3), and states of affairs (1). Normative claims can be conditional (4). The applicability of a norm may be constitutive of an activity ((5) – one is not playing soccer if players may use their hands). Or it may just be constitutive of doing it well (6). Normative claims are not restricted to moral claims; they can be legal (7), aesthetic (8); means–end (9); etc.

Issues involving normativity arise regarding language and linguistics in a variety of ways. Four particularly prominent questions are discussed below: May linguistics itself issue normative pronouncements concerning language and language use? Are semantic properties inherently normative? Are speech acts and pragmatic phenomena more generally inherently normative? What linguistic properties do the terms used to express normative claims themselves have?

Prescriptive Versus Descriptive Linguistics

Language users often turn to dictionaries to answer questions concerning how a word should be used. They view dictionaries as compendia of prescriptions, not descriptions. Linguists, however, generally do not aspire to normative conclusions in their research. They aim to describe and explain linguistic phenomena. On their view, linguistics, at least as they practice it, is and ought to be an empirical science. To the normative question 'what sort of pursuit should linguistics be?' they thus provide an answer that eschews normativity so far as the pronouncements of linguistics are concerned (*see* **Description and Prescription**).

It is a distinct question, however, whether the scientific study of language, though it should not enter normative claims, must also prescind from examining and adverting to normative phenomena. Canons of politeness, for example, are normative. But they impact language and language use. (*see* **Politeness**). For instance, they affect turn-taking in discourse and can become lexically, morphologically, and syntactically encoded. They thus seem important objects of study for linguists. Some philosophers of science suggest that naturalistic inquiry cannot accommodate intrinsically normative phenomena. Others object that this represents an overly narrow conception of naturalistic inquiry. This is an instance of a larger (venerable) debate concerning the status of the 'human' (or, social) sciences and their relation to the natural sciences (cf. Martin and McIntyre, 1994: Part III).

Semantics and Normativity

It is often claimed that semantic properties are intrinsically normative, in some manner encoding standards of correctness. Though fleshed out in various ways, the defense typically involves arguments purporting to show that the possession of a semantic property entails or is entailed by something normative.

For example, it is sometimes suggested that, if 'dog' denotes dogs, then one ought to apply the term only to dogs. If one applies the term to a cat, one has made a mistake (cf. Kripke, 1982). Here, it is claimed that possession of a semantic property has normative consequences. However, it is not generally the case that, if one should or should not do something with an X, then Xs are intrinsically normative; one ought not throw rocks at people, but rocks are not intrinsically normative – nor is the property of being a rock or

any of a rock's intrinsic properties. What matters is whether the normative conclusion follows *just* from the thing's being X. That one should not throw rocks at people follows, not just from what rocks are like, but from that and one's obligation not to cause bodily harm.

The question is thus whether the possession of a semantic property like 'denotes dogs' is sufficient in and of itself to generate obligations. Arguably, it is not: that one ought to apply 'dog' only to dogs would seem to follow, not just from its possessing the semantic property of denoting dogs, but from that and the further assumption that one ought to aim at truth. Perhaps one indeed ought to aim at truth; perhaps not always (maybe there are circumstances in which lying is justified – for example, to confuse a would-be cat-killer). But if the assumption that one should aim at truth must be added, then the normative conclusion does not follow from the semantic claim alone (Horwich, 1998: Chapter 8).

Others claim that semantic properties are intrinsically normative because *what makes it the case* that terms have their semantic properties are certain normative phenomena. The possession of semantic properties is thus alleged to be entailed or determined by the obtaining of normative facts. For example, some argue that semantic claims (such as that 'dog' denotes dogs) obtain in virtue of a language user's being disposed to apply 'dog' to dogs in appropriate circumstances – where what makes circumstances appropriate may include how things optimally ought to be when applying such a term. Others, however, attempt to show that, contrary to such claims, one can 'naturalize' semantic content. They maintain that terms have their semantic properties in virtue of facts that can be characterized nonnormatively (cf. Loewer, 1996).

One project in foundational semantics that would reject 'naturalization' thus construed is inferentialism (Brandom, 1994). According to it, semantic claims (such as 'dog' denotes dogs) obtain in virtue of it being the case that certain inferences involving the term would be correct to draw, and certain inferences would not. Logical terms provide the best cases for this approach: the claim would be that 'and' means what it does in virtue of the validity of inferences of the form (1) 'A and B' implies A and (2) A, B implies 'A and B.' Among the challenges is to extend this strategy to other terms. In the case of 'dog,' the relevant inferences would include not only transitions (in appropriate circumstances) from the presence of dogs to 'Those are dogs,' but also the inference from 'Those are dogs' to 'Those are mammals' – and much more besides.

Pragmatics and Normativity

Even if the meanings of expressions are not inherently normative, one might claim that what speakers do with expressions is inherently normative. Human language use, at least in core cases, is a species of intentional action, and all such action is done for reasons. One's reasons for acting are subject to normative assessment; they may or may not be *good* reasons. The intentional nature of linguistic action figures prominently in speech act theory (Austin, 1975) and accounts of conversational implicature (Grice, 1989). It also provides one motivation for developing game-theoretic models of language use.

Consider first the study of speech acts. It is often claimed that, for the utterance of a sentence to constitute the performance of a speech act, it must be performed intentionally by a speaker beholden to certain norms, with specific norms attaching to specific speech acts. For example, for the utterance of a particular sentence to constitute an assertion, the speaker must represent herself as having warrant for the truth of the claim asserted, with the result that she can be held accountable if the claim is not true or at least was not asserted on sufficient grounds. The transmission of truth, or perhaps knowledge, is said to be the aim or point of the practice of assertion. In this case, the norms constraining linguistic action would be constitutive of the kind of action at issue (cf. Williamson, 1996).

In performing a specific speech act such as assertion, it is often one's intention to communicate more than just what one asserts. (Sometimes one intends to communicate something *instead* of what one makes as if to assert.) For example, in answer to the question 'Do you think John is coming?' one might utter the sentence 'There's a lot of snow on the roads' in order both to assert that there's a lot of snow on the roads and to communicate that John is probably not coming. Grice (1989) argued that such 'conversational implicatures' are possible because of language users' sensitivity to the reasons for which a cooperative speaker would utter particular sentences in particular conversational contexts. He articulated a set of maxims for cooperative language use – for example, that one be as informative as possible, all else being equal, but also that one refrain from prolixity, all else being equal – that parties to a conversation tacitly assume one another to be observing. Speakers can then rely on hearers to infer an implicature, as in the case above, when doing so preserves the assumption of cooperation. Such maxims are norms that specifically apply to cooperative conversations and that enable speakers and hearers to discern the specific conversational reasons behind linguistic actions.

In the preceeding discussion, statistical norms were sharply distinguished from norms for how things ought to be. But statistical norms, like other nonnormative facts, can have normative upshot; how things are affects what means one should take to achieve one's ends. Conforming to a trend, for example, can in some cases increase the likelihood of obtaining an outcome. This is certainly so with language. Suppose one has an interest in one's utterances being understood. One then has reason to speak in a way that will promote understanding. But then, insofar as there exist statistical norms concerning pronunciation, assignment of meaning, expected prolixity, and other linguistic matters, there is reason to conform to those norms, since those norms will correlate with other language users' expectations. This provides one rationale for using game-theoretic techniques to study both the development of linguistic norms (in the statistical sense) and the ways speakers deploy language on particular occasions (see, e.g., Nowak and Komarova 2001, and with reference to pragmatic phenomena, Parikh, 2001).

Linguistic Properties of Normative Terms

We express normative claims – like any other claims – by using language. Normative expressions such as 'ought,' 'justified,' and 'you should not do that' are thus themselves proper objects of linguistic theorizing. Three examples are the use of deontic logic to capture the content of normative lexical items, expressivism as a non-truth-conditional analysis of normative sentences, and the study of generics.

Deontic logic – a branch of intensional logic – studies the logical relationships among normative expressions. 'It's obligatory that one X,' for example, implies 'It's not forbidden that one X.' Logicians studying such expressions construct formal languages with axioms and inference rules that capture these relations. Such investigations can be construed as contributions to the lexical semantics of the normative terms (see Føllesdal and Hilpinen, 1971).

Expressivism in its most basic form is the doctrine that normative claims such as 'Murder is wrong' do not purport to determine truth-conditions, but rather express an attitude toward a certain kind of action – in this case a negative attitude toward murder. Normative claims on this view are thus no more liable to assessment for truth or falsity than such aesthetic expressions as 'Chocolate: yum!' Expressivism might be motivated by the intuition that normative claims – for example, moral claims – do not purport to express objective facts. Expressivism, however, has difficulty accommodating embedded normative claims. The sentence 'If murder is wrong, then what Mary did was wrong' does not itself express any attitude to murder. This would seem to indicate that the expression of an attitude is not itself among the semantic properties of the expressions used. Moreover, the following argument seems deductively valid: murder is wrong; if murder is wrong, then what Mary did was wrong; therefore, what Mary did was wrong. It's natural to elucidate this validity by viewing the argument as an instance of the truth-preserving inference schema *Modus Ponens*. But this can seem blocked if normative claims do not determine truth-conditions. (For discussion from the perspective of a more sophisticated version of expressivism, see Gibbard, 2003.)

Generic claims – such as 'Dogs have four legs' – provide an example of unobvious normativity. The sample sentence's truth, on the relevant reading, does not depend on the four-leggedness of *all* dogs. (Amputees do not witness its falsity.) Nor does the existence of *some* four-legged dogs suffice for its truth. The claim is not even that *most* dogs have four legs: a generic claim does not report a statistical norm. (It may be true that a spider's life has four stages, even if the vast majority of spiders never make it past the first.) The content of a generic claim is rather normative; *normal* dogs have four legs. Perhaps this is even in some sense how dogs ought to be – at least to conform to conversationally relevant expectations. (On generics generally, see Carlson and Pelletier, 1995.)

Norms and Correctness

S Bowerman, University of Cape Town, South Africa

© 2006 Elsevier Ltd. All rights reserved.

Traditionally, a language is thought to be structured along a set of rules, or 'norms,' that prevail over all aspects of the language: phonology, morphology, syntax, and semantics. These norms serve to make the language distinctive, intelligible within a wide speech community, and learnable. However, the precise definition of a norm is controversial and difficult. It is important to distinguish between those norms (which I shall call 'descriptive norms') that enable us to describe a language or variety from observation of data, and prescriptive or 'pedagogical norms,' which often reflect some abstract ideal of how a language should be used, rather than the actual practice of native speakers of that language.

Norms and Linguistics

Descriptive norms, then, are intuitive (Itkonen, 1994: 2835) and are acquired rather than learned. Pedagogical norms, on the other hand, are learned and might not be intuitive; this is especially evident when a learned norm does not reflect the practice of the speakers of a language (the traditional prohibition on ending English sentences with a preposition is a good example). Languages are naturally subject to variation and change; without some norms, established naturally or by convention, it is likely that there would be so much individual variation that mutual intelligibility would be nearly impossible. Prescriptive norms often intend to fix the language in a certain state, so that any variation from them would be a violation of the norms of the language, and therefore 'incorrect.'

Norms or rules pertaining to linguistic composition can be quite easily identified across the spectrum of language. For example, the use of the suffix *-s* to form the regular English plural can be described as a 'norm.' Likewise, the inversion of the first auxiliary in an English sentence is the norm for creating a *yes-no* interrogative form. Phonology, too, has an identifiable set of norms: any native (or competent) speaker of English, for instance, would recognize that the sound sequence *belk* is a permissible word in English, even though it is not yet a word; under current norms, however, the sequence *blzr* is not a permissible sound structure to form a word in English. All of these norms are describable and reflect the current state of (some variety of) the language; and all of these norms are subject to change.

Norms also apply to other aspects of linguistic behavior. For example, it is a norm that one would answer a question with a statement appropriate to the question; anyone who does not do so would be behaving against the norms, or 'incorrectly.' However, where we are dealing with aspects of human behavior, rather than the abstract 'structure' of a language *per se*, the boundary between 'norms' and 'correctness' becomes even more blurred.

The concept of the linguistic norm is a crucial one for linguists in both the prescriptive and descriptive traditions. For descriptivists, norms are the means by which a language is described. Thus, the standard practice for the composition of a verb phrase in English is that the complement follows the verb; this can be rewritten as the rule VP → V.DP in a description of the language. Any deviation from this norm is ungrammatical (or, if grammatical, must be explainable by another norm). Likewise, VP → DP.V is the norm for a Japanese VP, as the complement normally precedes the verb. However, it is important to note that speakers in context do not always make consistent use of the 'rules': utterances may consist of 'ill-formed' sentences and phrases that are perfectly well understood in context and are not noted as unusual. This also applies to conversational behavior, in that a question form could legitimately be used

Norms and Correctness

Traditionally, a language is thought to be structured along a set of rules, or 'norms,' that prevail over all aspects of the language: phonology, morphology, syntax, and semantics. These norms serve to make the language distinctive, intelligible within a wide speech community, and learnable. However, the precise definition of a norm is controversial and difficult. It is important to distinguish between those norms (which I shall call 'descriptive norms') that enable us to describe a language or variety from observation of data, and prescriptive or 'pedagogical norms,' which often reflect some abstract ideal of how a language should be used, rather than the actual practice of native speakers of that language.

Norms and Linguistics

Descriptive norms, then, are intuitive (Itkonen, 1994: 2835) and are acquired rather than learned. Pedagogical norms, on the other hand, are learned and might not be intuitive; this is especially evident when a learned norm does not reflect the practice of the speakers of a language (the traditional prohibition on ending English sentences with a preposition is a good example). Languages are naturally subject to variation and change; without some norms, established naturally or by convention, it is likely that there would be so much individual variation that mutual intelligibility would be nearly impossible. Prescriptive norms often intend to fix the language in a certain state, so that any variation from them would be a violation of the norms of the language, and therefore 'incorrect.'

Norms or rules pertaining to linguistic composition can be quite easily identified across the spectrum of language. For example, the use of the suffix *-s* to form the regular English plural can be described as a 'norm.' Likewise, the inversion of the first auxiliary in an English sentence is the norm for creating a *yes-no* interrogative form. Phonology, too, has an identifiable set of norms: any native (or competent) speaker of English, for instance, would recognize that the sound sequence *belk* is a permissible word in English, even though it is not yet a word; under current norms, however, the sequence *blzr* is not a permissible sound structure to form a word in English. All of these norms are describable and reflect the current state of (some variety of) the language; and all of these norms are subject to change.

Norms also apply to other aspects of linguistic behavior. For example, it is a norm that one would answer a question with a statement appropriate to the question; anyone who does not do so would be behaving against the norms, or 'incorrectly.' However, where we are dealing with aspects of human behavior, rather than the abstract 'structure' of a language *per se*, the boundary between 'norms' and 'correctness' becomes even more blurred.

The concept of the linguistic norm is a crucial one for linguists in both the prescriptive and descriptive traditions. For descriptivists, norms are the means by which a language is described. Thus, the standard practice for the composition of a verb phrase in English is that the complement follows the verb; this can be rewritten as the rule VP → V.DP in a description of the language. Any deviation from this norm is ungrammatical (or, if grammatical, must be explainable by another norm). Likewise, VP → DP.V is the norm for a Japanese VP, as the complement normally precedes the verb. However, it is important to note that speakers in context do not always make consistent use of the 'rules': utterances may consist of 'ill-formed' sentences and phrases that are perfectly well understood in context and are not noted as unusual. This also applies to conversational behavior, in that a question form could legitimately be used

to answer a question form. One of the most interesting things about linguistic norms is perhaps the fact that, in spoken language, they tend to be inconsistently applied – or even flouted – by native speakers but are always readily identifiable by them.

Indeed, it is in written language where norms are more easily identified and much more rigid. Context can be taken for granted in most speech situations but must be conveyed in the text in written language. There are more cues to aid the hearer in speech, which allows the norms to be more fluid. Love (1994: 773) points out that far more emphasis is placed on correctness via prescriptive norms in a literate society. Unlike speech, which is a passing event (except in the memory), writing provides a permanent record that may be studied and from which conclusions as to how the language should be used may be drawn. Moreover, writing is often based on a standardized language variety and usually contains far fewer dialectal variations than speech, so that, even where dialectal differences may make two varieties of the same language unintelligible, the written varieties are identical (Gleason, 1970: 425).

Correctness and Prescriptivism

'Correctness' can be thought of as insistence upon the consistent application of linguistic norms in the use of a language. A piece of language may be understood easily enough, but not 'correct,' because of some deviation from prescribed norms in terms of pronunciation, structure, or meaning. Even though this poses little threat to intelligibility, 'correctness' – meaning that there is a correct or proper way to use a language – has played a significant role in the histories of most languages, particularly those that are written. This idea of correctness stems from the recognition of, or rather, the attempt to describe, a set of rules that pertain to a language and generally pervades all levels of language. Thus, there is a feeling that there is a proper way to pronounce words (e.g., *car* as [kɑːɹ], not [kɑː] in U.S. varieties); that some morphological processes are more appropriate than others (e.g., *width* rather than *wideness*); that certain syntactic norms must be rigorously enforced (e.g., sentences may not end with prepositions); that certain uses of language are more polite than others; and so forth. Within the wide ambit of that thing we call a 'language,' there is a huge degree of individual, regional, and social variation; the idea of what is correct or proper generally becomes attached to the general set of prevailing linguistic norms associated with an influential or high-status group. This is often imposed upon the whole speech community as the 'standard' associated with the public face of that language, and is the variety usually transmitted to foreigners.

Languages change in time as well as space, and this naturally means that the norms change too. Thus, the insistence upon a correct or proper way to use written language can have the effect of freezing a language in time. Indeed, the effects of this can be seen in languages that have effectively been frozen in time for ritual purposes: e.g., Latin reflects a step in the development of the Romance languages but is no longer mutually intelligible with them, and Koranic Arabic differs widely from the modern vernaculars.

It is often the stated goal of language academies and other organizations devoted to language preservation to keep the language in a state of 'purity.' The source of the notion that a language is 'pure' is not clear, but usually language movements advocating a rigid prescriptivism seek to protect the language (and its community) from outside influence. For example, the Academie Française sought to limit the influence of English on the French language. Similarly, other language movements have sought to limit the influence of modernism, etc.

Norms and Current Linguistic Theory

Despite the vast amount of variation and change that occurs across and within languages, the study of linguistic typology suggests that all languages are based on a set of universal norms. Although this set would appear to be extremely limited, the large number of implicational universals that has been identified suggests that there is in fact a set of norms that governs linguistic variation.

Similarly, 'generativist linguists' theorize that there exists a set of universal principles, comparable to norms, that govern what is a 'potential human language' and parameters that govern linguistic variation and change, all of which are available through an innate language faculty or 'universal grammar.' Beginning with Saussure, the trend in modern linguistics has been away from prescriptivism, in the direction of descriptivism. The task of the descriptive linguist is to describe the 'spoken language'; however, as Love (1994: 79) points out, raw speech is full of phenomena that have to be discounted if one hopes to arrive at a description of the structure of the language. As already mentioned, the availability of context in the speech situation allows for much more fluidity in the application of norms; moreover, an utterance of the same sentence can mean different things on different occasions. This led to Saussure's distinction between 'langue' and 'parole' – ideas comparable to Chomsky's 'competence' and 'performance,'

respectively. For Chomsky, the speech situation is too full of extraneous, extralinguistic factors for speech alone to be a reliable indicator of what the language is like. Chomsky (1965: 3) insisted that language could only be perfectly studied through the hypothetical 'ideal speaker-listener,' living in a homogenous speech community and unaffected by extralinguistic (but entirely human) characteristics such as memory loss, shifts of attention, etc. More recently, he has developed this idea further to say that the state of any individual's language faculty is largely accidental, a result of personal experience, and "of no particular interest in itself" (Chomsky, 1995: 6f.). For Saussure, 'langue,' the invariant language of a speech community, is self-consistent, fixed, and invariant, existing in the collective mind of a speech community, although not consistently reflected in individual behavior (see Love, 1994: 779). The modern trend, then, is to perceive language itself as fundamentally normative (whether this is natural or conventional remains open for debate), and to describe language and languages in terms of these observed norms.

Norse and Icelandic

T Eythórsson, University of Iceland, Reykjavík, Iceland

© 2006 Elsevier Ltd. All rights reserved.

Terminology and Historical Relations

Norse, or more specifically Old Norse, is a branch of medieval North Germanic (*see* **Germanic Languages; Indo–European Languages**). Old Norse is another name for Old West Nordic, referring to the language spoken from about 800 A.D. to the late 14th century in Norway and to the mid-16th century in Iceland. It was also spoken in the Faroe Islands, and in the Norse (Viking) settlements in the British Isles and Greenland. In a narrower sense, Old Norse is often used interchangeably with Old Icelandic, since most of the transmitted texts were written in Iceland. Modern Icelandic is the language of Iceland from the mid-16th century onwards, and is spoken today by about 290 000 people (*see* **Iceland: Language Situation**).

The earliest documented stage of North Germanic is Ancient Nordic (also known as Proto-Nordic, Runic Norse, or Early Runic), attested in runic inscriptions in the Old Germanic writing system, the *futhark*, dating from about 150 to 800 A.D. (*see* **Runes**). Towards the end of this period North Germanic began to divide into Old Norse (gradually splitting into Old Norwegian and Old Icelandic), on the one hand, and Old East Nordic (Old Danish, Old Swedish, and Old Gutnish), on the other.

Despite being in origin a West Nordic language like Icelandic and Faroese, Modern Norwegian has developed characteristics that are closer to Danish and Swedish (*see* **Norwegian**). Therefore, the modern Nordic (or Scandinavian) languages can be grouped into Mainland Scandinavian (Swedish, Danish, and Norwegian) and Insular Scandinavian (Icelandic and Faroese).

From Old Norse to Modern Icelandic

The evidence for Old Norse almost exclusively comes from Norway and Iceland; early documentation of Faroese is much poorer, and that of Norse in other areas settled by Norsemen is very scanty. Early on, linguistic innovations started to separate Old Norwegian from Old Icelandic, but the differences between them did not become significant until the 14th century. The oldest Icelandic manuscripts do not display dialect variation, which may indicate leveling of putative preexisting dialect differences among the settlers, most of whom are reported to have come from Norway, either directly or via the British Isles. The most copious source of evidence involves prose texts

respectively. For Chomsky, the speech situation is too full of extraneous, extralinguistic factors for speech alone to be a reliable indicator of what the language is like. Chomsky (1965: 3) insisted that language could only be perfectly studied through the hypothetical 'ideal speaker-listener,' living in a homogenous speech community and unaffected by extralinguistic (but entirely human) characteristics such as memory loss, shifts of attention, etc. More recently, he has developed this idea further to say that the state of any individual's language faculty is largely accidental, a result of personal experience, and "of no particular interest in itself" (Chomsky, 1995: 6f.). For Saussure, 'langue,' the invariant language of a speech community, is self-consistent, fixed, and invariant, existing in the collective mind of a speech community, although not consistently reflected in individual behavior (see Love, 1994: 779). The modern trend, then, is to perceive language itself as fundamentally normative (whether this is natural or conventional remains open for debate), and to describe language and languages in terms of these observed norms.

Terminology and Historical Relations

Norse, or more specifically Old Norse, is a branch of medieval North Germanic (*see* **Germanic Languages; Indo–European Languages**). Old Norse is another name for Old West Nordic, referring to the language spoken from about 800 A.D. to the late 14th century in Norway and to the mid-16th century in Iceland. It was also spoken in the Faroe Islands, and in the Norse (Viking) settlements in the British Isles and Greenland. In a narrower sense, Old Norse is often used interchangeably with Old Icelandic, since most of the transmitted texts were written in Iceland. Modern Icelandic is the language of Iceland from the mid-16th century onwards, and is spoken today by about 290 000 people (*see* **Iceland: Language Situation**).

The earliest documented stage of North Germanic is Ancient Nordic (also known as Proto-Nordic, Runic Norse, or Early Runic), attested in runic inscriptions in the Old Germanic writing system, the *futhark*, dating from about 150 to 800 A.D. (*see* **Runes**). Towards the end of this period North Germanic began to divide into Old Norse (gradually splitting into Old Norwegian and Old Icelandic), on the one hand, and Old East Nordic (Old Danish, Old Swedish, and Old Gutnish), on the other.

Despite being in origin a West Nordic language like Icelandic and Faroese, Modern Norwegian has developed characteristics that are closer to Danish and Swedish (*see* **Norwegian**). Therefore, the modern Nordic (or Scandinavian) languages can be grouped into Mainland Scandinavian (Swedish, Danish, and Norwegian) and Insular Scandinavian (Icelandic and Faroese).

From Old Norse to Modern Icelandic

The evidence for Old Norse almost exclusively comes from Norway and Iceland; early documentation of Faroese is much poorer, and that of Norse in other areas settled by Norsemen is very scanty. Early on, linguistic innovations started to separate Old Norwegian from Old Icelandic, but the differences between them did not become significant until the 14th century. The oldest Icelandic manuscripts do not display dialect variation, which may indicate leveling of putative preexisting dialect differences among the settlers, most of whom are reported to have come from Norway, either directly or via the British Isles. The most copious source of evidence involves prose texts

transmitted in manuscripts in the Latin script, the earliest dating from the 12th century. Particularly important for the study of Old Icelandic phonology is the so-called First Grammatical Treatise (ca. 1150), an outstanding work in terms of its scientific precision and methodological rigor (*see* **First Grammatical Treatise**). A further source is found in two types of Old Norse poetry, the 'eddic' and 'scaldic' poems. Both types of poetry preserve numerous archaic features, in part due to their metrical form, and thus they represent a linguistic stage predating the earliest written texts. Finally, there are runic inscriptions in Old Norse, mostly from Norway but also from Iceland. There has been an unbroken written tradition from Old Norse to Modern Icelandic.

Phonology

Ancient Nordic had five vowels, which could be long or short, and three diphthongs. Due to umlaut, breaking and other sound changes, however, Old Norse had, by the mid-12th century, developed a system of twenty-six vowel phonemes and three diphthongs. In this system not only vowel quantity but also nasality were distinguished, but the latter distinction (which only pertained to long vowels) was lost early on. In the following centuries some further changes occurred in the vowel system, the most important being the loss of distinctive vowel length. This change, known as the 'great quantity shift,' took place in Icelandic in the 16th century, but in the three preceding centuries it had affected most of the other Nordic languages. As a result of these changes, the Modern Icelandic vowel system, consisting of eight vowel phonemes and five diphthongs, is very different from that of Old Norse, although the effects of the changes are obscured by conservative orthography. By contrast, the consonant system has remained more stable from Old Norse to Modern Icelandic. Certain characteristics of Modern Icelandic consonants are rare in other languages, e.g., preaspiration of voiceless stops (*happ* [hahp] 'luck') and devoicing of sonorants (*milt* [mi̥lt] 'mild,' *fínt* [fi̥nt] 'fine'). However, such sounds also occur in Faroese and some Norwegian dialects, which may point to a common origin in Old Norse. Moreover, similar characteristics in neighboring languages, Scots Gaelic and North Sámi (Saami, Northern), are possibly due to contact between these languages and Old Norse.

Morphology

Old Norse is distinguished from its Germanic relatives by two notable morphological innovations. The first involves the development of a definite article, which can be free or suffixed to the noun; in either case the noun and the article both inflect. There is no indefinite article in Old Norse, a situation which has been preserved in Modern Icelandic but not in the other modern Nordic languages. The second innovation is 'middle' verbs characterized by an ending which originated as an enclitic reflexive pronoun. The middle has various meanings, such as reflexive, reciprocal, anticausative, and passive. The last meaning is uncommon in Old Norse and Modern Icelandic, but has become the dominant one in Mainland Scandinavian.

Otherwise, most morphological categories known from other Old Germanic languages recur in Old Norse and, by and large, in Modern Icelandic as well. These include the four cases of nouns, pronouns, and adjectives, and three degrees of comparison for most adjectives and some adverbs. Nouns are inherently masculine, feminine, or neuter, but pronouns and adjectives agree in gender with the noun they modify. Finite verbs are inflected in three persons, two tenses (present, past), and three moods (indicative, subjunctive, imperative). The nonfinite verb forms comprise the infinitive and the present and past participles.

There are two numbers (singular and plural) in Old Norse, with the sole exception of the first and second person personal and possessive pronouns that preserve the dual number as well. In Icelandic the pronominal dual replaced the plural forms, whereas the old plural forms were restricted to honorific (formal) usage; in the past few decades the use of the honorific forms has decreased so that they are by now obsolete.

Syntax

Old Norse is a verb second (V2) language: the finite verb obligatorily occurs no later than in second position in all main clauses. V2 is an innovation in Germanic *vis-à-vis* other Indo-European languages, which may originally have been limited to certain main clause types and then generalized to all main clauses. Moreover, in Old Norse the finite verb occurs in second position in subordinate clauses as well, presumably due to an extension of the main-clause pattern. This pattern ('symmetric V2') has been preserved in Modern Icelandic but not in Mainland Scandinavian.

Old Norse also has verb-initial clauses (V1), e.g., in direct questions, commands (imperatives), and conditional clauses. Declarative main clauses exhibiting V1 are frequent in narrative contexts ('narrative inversion').

In noun phrases (NPs), adjectival and pronominal modifiers regularly precede the head noun in Old Norse, but they may also follow it. Possessive genitives, on the other hand, generally follow the head noun, and this is also the case in Modern Icelandic.

In Old Norse the order of the nonfinite verb relative to an object in the verb phrase (VP) can be either verb-object (VO) or object-verb (OV). Such variable VP order also occurs in Old English. In Modern Icelandic OV orders were lost rather abruptly in the beginning of the 19th century, several hundred years later than in most other Nordic languages. The only exceptions to the strict VO pattern in Modern Icelandic are found with negative objects, which obligatorily precede the verb, and quantified objects, where either order may occur.

In the neutral word order in both main and subordinate clauses the subject occurs initially, immediately followed by the finite verb in second position (V2). In clauses containing a fronted nonsubject, the subject regularly follows the finite verb, although it may also occur further to the right, and even be extraposed to the end of the clause. Topicalization of VPs is ungrammatical in Modern Icelandic and seems not to be attested in Old Norse prose. However, fronting of nonfinite verbs (past participles, infinitives), as well as other head-like elements, is very common. This is 'stylistic fronting,' which only occurs in clauses that do not contain an overt subject ('subject gap').

As in other Germanic languages with morphological case, in Old Norse and Modern Icelandic subjects are typically in nominative case, direct objects in accusative case, and indirect objects in dative case. Various other patterns exist, however; in particular, dative objects are more common than in other Germanic languages. A further noteworthy characteristic is the occurrence of oblique (or 'quirky') subjects in Modern Icelandic (and Faroese). The status of the corresponding oblique NPs in Old Norse has been a matter of some controversy, but it is clear that in some respects they pattern syntactically with nominative subjects rather than with unambiguous objects. There is a tendency among some speakers of Icelandic to generalize dative case at the expense of accusative on some oblique subjects ('dative sickness'), or to replace the oblique case by nominative ('nominative substitution').

The emergence of a nonreferential or 'expletive' element, homonymous with the singular neuter pronoun *það* 'it,' was an innovation that gained ground in Icelandic in the latter half of the 18th century. About the same time, referential null arguments (*pro*-drop), occurring under certain rather well-defined conditions in Old Norse and early Modern Icelandic, were largely lost. A further innovation, apparently much more recent, is the 'new impersonal construction' (also called the 'new passive'), which has passive verb morphology (an auxiliary verb 'be' plus a past participle) but an accusative object in postverbal position. This phenomenon does not seem to have a match in other Germanic languages, but there are typological parallels further afield, e.g., in Polish and Irish (Gaelic, Irish).

In archaic Old Norse (eddic and scaldic poetry), negation was expressed by a verbal prefix *ne* 'not,' also found in other Old Germanic languages. At this early stage of Old Norse the prefix could cooccur with a suffix (*-a* or *-at*) attaching to the finite verb, so that together the prefix and the suffix formed a discontinuous negation. These forms were lost early on, and negation came to be expressed by sentence adverbs (cf. Icelandic *ekki*, Danish *ikke* 'not').

Vocabulary

The Old Norse vocabulary belongs to the common Germanic stock. In addition to the inherited material, it contains a number of cultural loans from neighboring languages that the Vikings were in contact with. In Icelandic a few Celtic loanwords date from the earliest period, which is comprehensible in light of the fact that some of the Norse settlers came to Iceland via the British Isles, where they had been living in the proximity of Celts. Christianity, introduced in Iceland in the year 1000, led to an influx of new loanwords relating to religious and scholarly concepts, either directly from Latin or through intermediaries, especially Old English and Old Saxon. Further contact, especially trade and translations of the literature of chivalry, brought new loans from Low German that were mostly transmitted via Norwegian, although some of them were ultimately of French or Latin origin. In the wake of the Reformation in the mid-16th century more loanwords entered the language, in particular from High and Low German. The transmission mostly followed via Danish, which remained the most influential foreign language in Iceland until the middle of the 20th century. Since then the influence of English has been increasing steadily. A recent survey indicates that today, English is used more on a daily basis in Iceland than in any other Nordic country.

Despite long-standing contact with other languages, the vocabulary of Modern Icelandic is closer to Old Norse than that of any other Nordic language. This situation has in part been achieved by conscious effort. There is a long tradition of countermovement, dating back at least to the 18th century, against the infiltration of the language by foreign words and expressions, and language purism has been practiced as an active language policy since the mid-19th century. According to this policy, neologisms are created for new concepts (e.g., *sími* 'telephone,' *tölva* 'computer') rather than adopting words from other languages. Moreover, attempts have been made to resist

phonological, morphological, and syntactic changes, even by resurrecting some archaic patterns; while some of these attempts have been quite successful, others have failed. The old custom of patronymics (*Höskuldsson* 'son of Höskuldur,' *þórhallsdóttir* 'daughter of þórhallur') has been preserved to a large degree, with the active support of the public authorities. The use of metronymics is also an option, although much less common, but it seems to have increased somewhat in recent years (*Guðrúnardóttir* 'daughter of Guðrún,' *Hrafnbjargarson* 'son of Hrafnbjörg'). In the Icelandic telephone directory people are generally listed under their first name.

Archaism and Innovation in Icelandic

Icelandic is often claimed to be a 'conservative' language that has preserved many archaic features, and it is probably true that it is no more difficult for the modern Icelander to read the Old Icelandic 13th-century sagas than it is, for example, for speakers of English to read Shakespeare. Moreover, despite a certain amount of geographically distributed language variation, which mainly affects pronunciation, there appear never to have been well-defined local dialects in Iceland with numerous distinctive characteristics. Nor are there strong contrasts between a standard and substandard register, at least compared to many other countries. Some possible reasons for this stability may be the geographic isolation of the country, an active conservative literary tradition, and a strong tradition of language purism. Nevertheless, as indicated above, numerous innovations have taken place since Old Norse, mostly affecting the phonology and syntax of the language rather than its morphology.

North Mariana Islands: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The North Mariana Islands are a group of 14 isles located in the North Pacific Ocean about three-quarters of the way from Hawaii to the Philippines. Although sighted in 1521 by Ferdinand Magellan, who named them the Ladrones Islands (Thieves Islands), the Marianas were not settled by Europeans until 1668, when Spanish Jesuits arrived with the mission of converting the indigenous Chamorro people to Catholicism. The Mariana Islands, so renamed by the missionaries upon their arrival, remained a nominal possession of Spain until 1898, the year in which Germany bought them, with the exception of Guam, which was ceded to the United States. The islands belonging to Germany were seized by Japan in 1914 and were mandated to Japan by the League of Nations in 1920. During World War II, U.S. forces occupied the Marianas, and in 1947 the islands, exclusive of Guam, were included in the U.S. Trust Territory of the Pacific Islands. North Mariana residents approved separate status for the islands as a U.S. commonwealth in 1975. They became internally self-governing under U.S. military protection in 1978, and trust territory status was officially ended in 1986.

The official language of the North Mariana Islands is English, but there are three other national languages, all of them Austronesian: Carolinian (about 3000 indigenous Carolinians as of 2004), Chamorro (about 17 000 indigenous Chamorros as of 2004), and Tanapag (no estimates available). In fact, approximately 85% of the population of 69 221 (2000 census) speaks a language other than English at home, in part because the North Mariana Islands have a high number of workers of foreign extraction. For example, the governmental census of 1990 reported more than 20 000 Filipinos and 7000 Chinese (the possibility of having 'Made in USA' labels on products produced on the North Mariana Islands at low cost has attracted many industries). Carolinian, a Trukic language, is spoken on the islands of Agrihan, Anatahan, and Saipan. All Carolinian speakers on the latter are bilingual in Chamorro, and most also speak English. On Saipan, the capital island, there are also speakers of Tanapag, another Trukic language. They tend to have a limited bilingual proficiency in English or Chamorro, although it must be noted that in the traditionally Tanapag-speaking area, those under 30 years of age do not speak Tanapag but use Chamorro instead. There is now an attempt to promote Tanapag. Chamorro is spoken on the islands of Rota, Tinian, and Saipan, where it is also used as a trade language; Chamorro speakers present some bilingualism in English. The only television station and the 6 radio stations in the North Mariana Islands broadcast mainly in English, although the other national languages are also featured. Reception of satellite television channels is easy on the islands.

North Philippine Languages

L A Reid, University of Hawai'i, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

There are reported to be around 70 languages spoken in the north of the Philippines, nearly half of the total number of Philippine languages (Grimes and Grimes, 2000). For the purpose of this article, these languages include all of those spoken to the north of Manila, on the island of Luzon, and on the islands of the Batanes group, located in the Bashi Channel between Luzon and Taiwan. All of these languages belong to the branch of the Austronesian family, commonly referred to as Malayo-Polynesian (but in some works as Extra-Formosan), that began with the movement of Austronesian Neolithic seafaring people from what is now called Taiwan to eventually settle all of the Philippines and ultimately the rest of the Pacific. Recent archaeological evidence (Bellwood *et al.*, 2003: 158) suggests that this movement began around 4000 years ago, with a small group of Austronesian people leaving the eastern coast of Taiwan, settling the Batanes Islands and eventually reaching the northern coast of

North Philippine Languages

L A Reid, University of Hawai'i, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

There are reported to be around 70 languages spoken in the north of the Philippines, nearly half of the total number of Philippine languages (Grimes and Grimes, 2000). For the purpose of this article, these languages include all of those spoken to the north of Manila, on the island of Luzon, and on the islands of the Batanes group, located in the Bashi Channel between Luzon and Taiwan. All of these languages belong to the branch of the Austronesian family, commonly referred to as Malayo-Polynesian (but in some works as Extra-Formosan), that began with the movement of Austronesian Neolithic seafaring people from what is now called Taiwan to eventually settle all of the Philippines and ultimately the rest of the Pacific. Recent archaeological evidence (Bellwood *et al.*, 2003: 158) suggests that this movement began around 4000 years ago, with a small group of Austronesian people leaving the eastern coast of Taiwan, settling the Batanes Islands and eventually reaching the northern coast of

Luzon. The Philippines was already occupied at that time by a large number of Negrito bands of hunter-gatherers, most of which are already extinct or which have been completely assimilated by the technologically superior inmigrating Austronesians. There are still, however, more than 20 groups of Negritos located in relatively remote areas of the northern Philippines. About 15 of these groups, variously called Agta, Alta, and Arta, live in and around the Sierra Madre mountain range, with five or more groups called Ayta scattered around the Sambal mountain range in the west of Luzon. All Negrito groups adopted the language of their closest Austronesian neighbors in the distant past (Reid, 1987), but today they have diverged to the point where they speak languages which are clearly distinct from those of their neighbors. The Negrito languages are now highly endangered, because of the continuing pressure to integrate with their non-Negrito neighbors and the influence of the local trade languages.

Three of the languages in the northern Philippines, Ilokano (Ilocano) (with 6 636 000 speakers, or approximately 8.7% of the total Philippine population of 76 504 000, according to the National Statistics Office of the Philippines 2000 Census of Population and Housing), Kapampangan (Pampangan) (with 2 066 800 speakers, or 2.7%), and Pangasinan (with 1 185 600 speakers, or 1.5%) are referred to as 'major' languages, based on number of speakers. Of these, Ilokano is most important, being widely spoken as a second language and used as a language of wider communication throughout the north of Luzon. These three languages belong to three different subgroups of Philippine languages. Ilokano is a first-order branch of the major language family in the north of the Philippines, referred to as northern Luzon or Cordilleran (Reid, 1979). Pangasinan is a member of the Central–Southern branch of the same family, while Kapampangan groups with the Sambalic languages, and possibly ultimately with the Batanic languages Itbayat and Ivatan, spoken in the far north of the Philippines (and their closely related language, Yami, spoken on Lányŭ or Orchid Island in Taiwan).

Tagalog has been used for a long period as a lingua franca in some areas of the northern Philippines, particularly on the eastern coast of Luzon, as far north as Paranan, with extensive influence on languages spoken in the area. In addition, in the guise of Filipino, the national language of the Philippines, the language has in recent years been moving out of the classroom throughout northern Luzon and into the daily lives of the younger generation, competing with Ilokano as a tool for communicating with outsiders.

The northern languages of the Philippines have a type of syntax that is found throughout the country (Reid and Liao, 2004). Predicates typically occur at the beginning of constructions, only allowing topicalized NPs to precede them. Noun phrases are typically introduced by one of a series of short, often monosyllabic forms which specify semantic features of the lexical head of the phrase, whether it is a common or personal noun, whether it is singular or plural, and in some languages its spatial or temporal relationship to the speaker. This form may also mark the case of the noun. Nominative (or absolutive) NPs are typically unmarked for case when they are lexical nouns, but are case marked when a pronominal substitute replaces them.

Each of the languages is morphologically ergative, with the patientlike noun phrase of transitive sentences being marked in the same way as the single argument of intransitive sentences, while the agentlike noun phrase of transitive sentences is marked in the same way as that of genitive constructions within a noun phrase.

Intransitive constructions are either monadic (having a single core argument) or dyadic (having two core arguments). The latter construction is amenable to an antipassive analysis, with the patientlike oblique argument being typically indefinite and marked with the same case marking as that used for locative noun phrases, unlike Tagalog, which marks such oblique NPs as genitives. Intransitive constructions are often referred to in the literature as 'actor–focus,' in that the morphology on the verb conveys the information that the nominatively marked NP is an 'actor.' Transitive constructions are typically considered to constitute at least four different types, 'goal focus,' 'locative focus,' 'instrument focus,' and 'benefactive focus,' depending on the morphology of the verb. Structurally these constructions are identical. They differ only in the semantic interpretation of the nominative NP of the sentence.

The northern languages of the Philippines tend to be more complex phonologically than other Philippine languages, which typically have only four or five vowels. Casiguran Dumagat Agta, for example, has developed an eight-vowel system, while Balangaw (Balangao), a Central Cordilleran language, is reported to have seven vowels. Karao, a southern Cordilleran language, has developed a series of fricatives /f/, /θ/, and /x/, which are unusual in Philippine languages. Several of the languages have very complex morphophonemic (sandhi) alternations. These include Ibanag, a northern Cordilleran language (Brandes and Scheerer, 1927–1928), and Karao and its sister language, Inibaloi (Ibaloi) (Brainard, 1994). Some dialects of Bontok (Bontoc), Ifugao, and Kalinga exhibit a complex range of often voiceless fricative or affricate prevocalic variants of their voiced

stops, /b/, /d/, and /g/, such as Guinaang Bontok [f], [ts], and [k̚ʰ] (Himes, 1984–1985), which because of the influence of English in the schools are losing their environmental conditioning and are now becoming separate phonemes in the languages (Reid, 2005).

Published text resources are available on a number of Cordilleran languages. Moreover, one of the finest dictionaries of a Philippine language is that of the central Cordilleran language Ifugao (Newell, 1993).

Norway: Language Situation

A R Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Norwegian is a North Germanic language, spoken by around 4.5 million inhabitants of Norway and a small number of speakers elsewhere, principally emigrant workers in other Scandinavian countries and the United States, although Ethnologue also notes groups of speakers in Canada, Ecuador, and the United Arab Emirates. The spoken language is characterized by rich dialectal variation, resulting historically from small groups of speakers spread across a large area with poor internal communications. Systematic dialectology has been a fertile branch of linguistic enquiry in Norway since the second half of the 19th century. Dialectal variation is a feature of all social groups and is relatively little stigmatized. The written language situation is more complex, and written Norwegian provides the classical example of language planning.

Following political independence from Denmark in 1814, several proposals for the establishment of a native written language were put forward. The two most vigorously pursued were the work of Ivar Aasen (1813–1896) on the one hand and Knud Knudsen (1812–1895) on the other. Aasen, with the backing of the State, created a new written language based on extensive and pioneering dialect fieldwork, and Knudsen pursued a policy of Norwegianization of the inherited Danish. Both policies had their opponents, but in 1885 the two varieties were placed on an equal footing by Parliament, leading to the written standards initially known as Landsmaal and Riksmaal, respectively, but renamed Nynorsk and Bokmål in 1929. Norwegian language politics in the first half of the 20th century were characterized by a series of official reforms intended to bring the two varieties closer together. The reforms of 1917 and 1938 in particular were underpinned by the ultimate goal of creating one common Norwegian, Samnorsk. This policy was never popular, and protests were especially vehement in the 1950s,

stops, /b/, /d/, and /g/, such as Guinaang Bontok [f], [ts], and [k̚ʰ] (Himes, 1984–1985), which because of the influence of English in the schools are losing their environmental conditioning and are now becoming separate phonemes in the languages (Reid, 2005).

Published text resources are available on a number of Cordilleran languages. Moreover, one of the finest dictionaries of a Philippine language is that of the central Cordilleran language Ifugao (Newell, 1993).

Norway: Language Situation

A R Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Norwegian is a North Germanic language, spoken by around 4.5 million inhabitants of Norway and a small number of speakers elsewhere, principally emigrant workers in other Scandinavian countries and the United States, although Ethnologue also notes groups of speakers in Canada, Ecuador, and the United Arab Emirates. The spoken language is characterized by rich dialectal variation, resulting historically from small groups of speakers spread across a large area with poor internal communications. Systematic dialectology has been a fertile branch of linguistic enquiry in Norway since the second half of the 19th century. Dialectal variation is a feature of all social groups and is relatively little stigmatized. The written language situation is more complex, and written Norwegian provides the classical example of language planning.

Following political independence from Denmark in 1814, several proposals for the establishment of a native written language were put forward. The two most vigorously pursued were the work of Ivar Aasen (1813–1896) on the one hand and Knud Knudsen (1812–1895) on the other. Aasen, with the backing of the State, created a new written language based on extensive and pioneering dialect fieldwork, and Knudsen pursued a policy of Norwegianization of the inherited Danish. Both policies had their opponents, but in 1885 the two varieties were placed on an equal footing by Parliament, leading to the written standards initially known as Landsmaal and Riksmaal, respectively, but renamed Nynorsk and Bokmål in 1929. Norwegian language politics in the first half of the 20th century were characterized by a series of official reforms intended to bring the two varieties closer together. The reforms of 1917 and 1938 in particular were underpinned by the ultimate goal of creating one common Norwegian, Samnorsk. This policy was never popular, and protests were especially vehement in the 1950s,

when the policy was being most actively pursued. Since the 1960s a series of developments has led to a gradual stalling of this policy, and in 2002 it was abandoned. Policy is now to leave the two varieties to develop in their own way, and while the Language Council has been disbanded, a new language agency is to be set up in its place, although its role and powers are, at the time of writing, unclear.

The majority of Norwegians use a moderately conservative form of Bokmål in writing, a variety that opponents of the reform process identify as Riksmål to distinguish it from the more radically engineered Bokmål. Riksmål has its own dictionary and an influential pressure group, The Norwegian Academy for Language and Literature. Advocates of a more conservative variety of Nynorsk, closer to the form originally proposed by Aasen, identify and champion another variety still, known as Høgnorsk. This has no official status, and its pressure groups are, at the time of writing, in some disarray.

Sociohistorical Setting

Norwegian together with Danish and Swedish constitute the Mainland Scandinavian languages, which, together with the Insular Scandinavian languages, Faroese and Icelandic, constitute the Scandinavian languages. The Scandinavian languages belong to the Germanic family of the Indo-European languages.

Norwegian is exceptional in having two officially recognized written standards. These are called *Bokmål* 'book language' and *Nynorsk* 'New Norwegian'. Bokmål is used by more than 80% of the population, whereas Nynorsk is used by less than 20%, mainly in the area stretching from the interior of southern Norway to the western coast. As for the spoken language, there is a rich variety of dialects, although all of them are mutually intelligible. The use of (nonstandard) dialects is widely accepted, even in more formal contexts. There is no officially recognized standard for the spoken language. It is important to note that Bokmål and Nynorsk are written standards that individuals choose largely irrespective of which dialectal variety they speak.

The two written standards have their background in the history of Norway. From 1380 to 1814, Norway was in a political union with Denmark, and Danish was used as a written language. Eventually, during the flourishing of nationalism after 1814, a Dano-Norwegian written standard was developed in the 19th century, bringing Norwegian elements into the Danish language. This standard gradually evolved into present-day Bokmål. Also, in the 19th century, a more radical approach was followed by Ivar Aasen (1813–1896). He developed a written standard based on the spoken dialects. This standard gradually evolved into present-day Nynorsk.

Today, Bokmål and Nynorsk are quite similar, but there are still certain spelling differences both regarding content words and grammatical morphology. In the description of Norwegian below, I will concentrate on the common structural features of the spoken language as a whole. All examples are written in the Nynorsk standard unless otherwise stated.

Morphology and Phonology

Finite verbs in Norwegian only show tense distinctions (past, present). There are two nonfinite verb forms, the infinitive and the past participle, and an adjectival

when the policy was being most actively pursued. Since the 1960s a series of developments has led to a gradual stalling of this policy, and in 2002 it was abandoned. The two written standards have their background in the history of Norway. From 1380 to 1814, Norway was in a political union with Denmark, and Danish was used as a written language. Eventually, during the flourishing of nationalism after 1814, a Dano-Norwegian written standard was developed in the 19th century, bringing Norwegian elements into the Danish language. This standard gradually evolved into present-day Bokmål. Also, in the 19th century, a more radical approach was followed by Ivar Aasen (1813–1896). He developed a written standard based on the spoken dialects. This standard gradually evolved into present-day Nynorsk.

Today, Bokmål and Nynorsk are quite similar, but there are still certain spelling differences both regarding content words and grammatical morphology. In the description of Norwegian below, I will concentrate on the common structural features of the spoken language as a whole. All examples are written in the Nynorsk standard unless otherwise stated.

Morphology and Phonology

Finite verbs in Norwegian only show tense distinctions (past, present). There are two nonfinite verb forms, the infinitive and the past participle, and an adjectival

present participle form. Example (1) shows the inflectional paradigm for the weak verb *kjøpe* 'buy'.

(1) kjøpe (infinitive) - kjøper (present) - kjøpte (past) - kjøpt (past participle)

Nouns have no productive case distinctions. However, they inflect for number (singular, plural) and definiteness (definite, indefinite), and there are three genders (masculine, feminine, neuter). Example (2) shows the paradigm for the feminine noun *geit* 'goat'.

(2)

	sg		pl
indef	geit	'goat'	geiter 'goats'
def	geita	'the goat'	geitene 'the goats'

As shown, definiteness is marked inflectionally as a suffix (*-ene* is a portmanteau morph expressing both definiteness and plurality). There is also a free-form indefinite article, varying according to gender; *ei* is the feminine form, as in *ei geit* 'a goat'.

Adjectives show agreement in gender (m/f and n) and number (sg, pl) in predicative and attributive positions.

As for phonological properties, Norwegian dialects have relatively rich vowel and consonant systems. Also, Norwegian dialects make extensive use of diphthongs. In most dialects, tones may have distinctive function.

Syntax

Norwegian is a SVO language with fixed word order, cf. (3).

(3) Mannen kjøper geita.
'The man buys the goat.'

Norwegian is also a verb second (V2) language, with the finite verb in second position in main declarative clauses. Thus, topicalization of the direct object in (1) yields *geita kjøper mannen* 'the goat the man buys' with the finite verb in the V2 position.

Auxiliary verbs are positioned between the subject and the main verb, as in *mannen har kjøpt geita* 'the man has bought the goat'. Finite auxiliary verbs follow the V2 pattern, cf. *geita har mannen kjøpt* 'the goat the man has bought'.

Adverbials are positioned in the middle field (sentence adverbials) or toward the end of the clause (predicate adverbials).

(4) Mannen har aldri kjøpt geiter på ein søndag.
'The man has never bought goats on a Sunday.'

Like other V2 languages, Norwegian shows an asymmetry between main and embedded clauses as to the relative distribution of sentence adverbial and finite verb, compare (4) to the embedded clause in *eg veit at mannen aldri har kjøpt geiter på ein søndag* 'I know that the man has never bought goats on a Sunday'.

Norwegian has a strict subject requirement in finite clauses. If there is no semantic subject, an expletive subject must be inserted.

(5a) Det regnar.
'It rains.'

(5b) Det står ei flaske på bordet.
it stands a bottle on table-the
'There is a bottle standing on the table.'

In most dialects, *det* 'it' is used as expletive subject in both meteorological (5a) and presentational (5b) sentences. Some dialects allow *der* 'there' as an expletive subject in addition to *det* 'it'.

Norwegian has two main types of passive, namely periphrastic passive and reflexive (*s-*) passive. Example (6b) is written in the Bokmål standard.

(6a) Geita blir kjøpt (av mannen) i dag.
goat-the becomes bought (by man-the) to day
'The goat is bought by the man today.'

(6b) Geita kjøpes (av mannen) i dag.
*goat-the buy-*s *(by man-the) to day*
'The goat is bought by the man today.'

Both types allow impersonal passive, as e.g., in *det blir kjøpt ei geit i dag* 'there is bought a goat today'.

There are two main types of interrogative clauses: yes/no questions (formed by placing the finite verb in initial position) and questions with a question word (with the question word placed in initial position). As for relative clauses, the most common type is introduced by the complementizer *som*. The complementizer is optional if the relativized position is a nonsubject, as in *geita (som) mannen kjøpte* 'the goat (that) the man bought'. Infinitival clauses are introduced by the infinitive marker *å* 'to', as in *mannen prøver å kjøpe geita* 'the man tries to buy the goat'.

Noun Phrases

J R Payne

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2848–2855, © 1994, Elsevier Ltd.

The term 'noun' is used to describe the class of lexical items whose prototypical members refer to entities (*chair, film, leg*), substances (*butter, concrete, blood*), and named individuals or locations (*John, Paris, France*). Traditionally, the term 'noun phrase' has then been used to describe any phrase consisting of a noun as its central constituent (or 'head') and capable of functioning as an argument (e.g., subject or object) in a sentence. Examples, in which the head nouns are in bold type, are: *my big red* **chair**, *the* **butter** *on the table*; **John**, *who is a lion-tamer*. The structure of noun phrases, which in many respects appears to be as complex as the structure of sentences, has become a controversial issue. While some linguists maintain that noun phrases are headed by nouns, others insist that the head of a noun phrase should be the 'determiner' (e.g., the definite article *the* in ***the*** *butter on the table*). According to these theorists, noun phrases should really be called 'determiner phrases.'

Nouns

Nouns can be divided into a number of important subclasses based on their grammatical and semantic properties. These subclasses relate to 'definiteness,' 'person, 'number,' and 'gender,' and they play a major role in determining what categories can cooccur with a given noun in a noun phrase.

Definiteness

One subclass of nouns, the subclass of proper nouns whose prototypical members refer to named individuals or locations, contains nouns whose reference is exclusively definite (i.e., when the speaker uses such a noun, he or she indicates that the hearer will be able to identify the proposed referent by locating some mutually manifest set which consists uniquely of the named individual or location). In some languages, proper nouns are used in conjunction with definite articles (e.g., Greek *o Yanis* (literally 'the John')), which gives a noun phrase whose definiteness is indicated both by the noun and by the article. In other languages, this redundancy may be avoided and a noun phrase may consist of the proper noun alone. The majority of proper nouns in English are of this type (e.g., *John, Paris, France*); however, some proper nouns (e.g., *the Hague, the Netherlands*) require the use of the article.

Opposed to proper nouns are common nouns, for which a distinction between definite and indefinite reference is possible. In indefinite reference, the speaker does not indicate to the hearer that the hearer will necessarily be able to locate a mutually manifest set in which the referent can be found. Indefinite reference is therefore either used when some new entity or substance is being introduced into the discourse (*Yesterday I saw* ***a film in which Meryl Streep played a New York psychiatrist***), or, if a set mutually manifest to both speaker and hearer can be found, to indicate that the referent is not unique within that set. In the sentence *John lost* ***a leg*** *in the war*, a set of two legs belonging to John may be mutually manifest to speaker and hearer, but if only one leg has been lost, indefinite reference is forced (see Hawkins, 1991).

In languages which distinguish between definite and indefinite articles, common nouns are able to occur with both. English has definite article *the* and indefinite articles *a* and *some*, giving a contrast between *the film* and *a film*, and *the butter* and *some butter*. With proper nouns, on the other hand, the use of contrasting definite and indefinite articles involves special interpretations: *I met* ***a John*** *at the party, but I don't think it's the person you mean*; ***The John that I met at the party*** *isn't present today*. In this case, it can be said that *John* has been reclassified as a common noun meaning something like 'person named John.'

Person

Distinctions of person are typically carried by a special class of nouns called personal pronouns, for example, *I* (first person singular), *you* (second person singular), *he/she/it* (third person singular), and *they* (third person plural) in English. These are similar to proper nouns in that they have definite reference, and do not cooccur with the definite article: **the you*.

Common nouns are neutral with respect to person. When nouns are used with standard determiners such as the articles or demonstratives, the noun phrase is usually interpreted as having third-person reference, but, as pointed out by Postal (1966), common nouns can also be combined in English with first-person plural *we* and second-person plural *you* to give noun phrases such as *we students* and *you students*. *We* and *you* can therefore be analyzed as first- and second-person person determiners in English, rather than as personal pronouns.

The neutrality of common nouns with respect to person is especially clear in Nama (Namibia). In Nama, all noun phrases contain a final marker

showing the person (as well as the number and gender) of the phrase. These markers are as follows (excluding special plural forms for mixed masculine and feminine phrases):

	Masculine			Feminine		
	Sing	Dual	Pl	Sing	Dual	Pl
First person	*-ta*	*-khom*	*-ge*	*-ta*	*-m*	*-se*
Second person	*-ts*	*-kho*	*-go*	*-s*	*-ro*	*-so*
Third person	*-b*	*-kha*	*-gu*	*-s*	*-ra*	*-di*

All these markers can be attached to any common noun, giving forms such as *ao-b* (man-third person singular) or *ao-khom* (man-first person dual). The third-person pronoun ||*i* behaves like any other noun, except of course that it can only be followed by third-person markers: ||*i-b* 'he,' ||*i-s* 'she,' etc. In addition, Nama also has determiners representing first and second person:

	Sing	Dual/Plural
First person	*ti*	*si*
Second person	*sa*	*sa*

These occur in initial position in first- and second-person noun phrases to give forms such as *si ao-khom* 'we (two) men.'

The first- and second-person 'personal pronouns' of Nama are formed simply by combining the relevant determiner and noun-phrase suffix, for example, *ti-ta* 'I,' *sa-kho* 'you (dual),' *si-khom* 'we (dual, excluding the hearer),' *sa-khom* 'we (dual, including the hearer).' In this case, as for English *we* and *you* (plural), it can be argued that no noun root as such is present in the noun phrase.

Number

Common nouns can be divided into those which can be counted (count nouns, like *chair*), and those which cannot (noncount nouns, like *butter*). Count nouns are able to cooccur with low numerals (*one* if they are singular, and *two* if they are plural), for example, *one chair, two chairs*. The use of low numerals with noncount nouns leads to unacceptability, for example, **one butter*, **two butters*, unless the noun in question is reclassified as a common noun with a different and countable interpretation, for example 'type of butter' or 'pat of butter.'

Count nouns may refer to sets consisting of one entity, or more than one entity, and this is the basis for number distinctions in language such as singular and plural. It is necessary, however, to distinguish between grammatical and semantic number. In English, collective nouns such as *family* are grammatically singular since they cooccur with grammatically singular forms of noun-phrase modifiers such as the singular indefinite article *a* and the singular demonstratives *this* and *that*: **a** *family*, ***this*** *family*, ***that*** *family*. Equally, *family* has a grammatically plural form *families* which cooccurs with the grammatically plural indefinite article *some* and the grammatically plural demonstratives *these* and *those*: ***some*** *families*, ***these*** *families*, ***those*** *families*. However, the grammatically singular form *family* can be thought of as referring semantically to a set consisting of its individual members, and this is reflected in the possibility of plural verb agreement: *All the family* ***are*** *coming to the wedding*.

Conversely, in some languages it is possible to find grammatically plural nouns which are semantically singular. For example, the Russian noun *časy* 'clock' is grammatically plural since it is modified by plural forms of the demonstratives *tot* 'that' and *etot* 'this': *te časy* (that-plural clock) 'that clock,' *eti časy* (this-plural clock) 'this clock.' Its semantic singularity is shown by its ability to cooccur with the numeral *odin* 'one,' which also has a grammatically plural form especially for use with such nouns: *odni časy* (one-plural clock) 'one clock'! English nouns like *scissors*, which appear similar (e.g., *those scissors, these scissors*), are grammatically plural, but noncount. One cannot say **one scissors*, but must add the count noun *pair* for the numeral to be possible: *one pair of scissors*.

While count nouns typically have both grammatically singular and grammatically plural forms in English, there are a few like *remains* which are only plural (**this remains, these remains*). Note that nouns like *sheep* are count nouns with both a singular and plural form (*this sheep, these sheep*): the singular and plural forms in this case just happen to be the same.

Gender

Nouns have different genders if they fall into different agreement classes, that is, if they cooccur with different agreeing forms of other categories such as noun-phrase modifiers, predicates, or pronouns.

In English, gender distinctions are absent from noun-phrase modifiers like adjectives, articles, and demonstratives, and from predicates. However, relative pronouns distinguish between 'personal' nouns which are referred to by *who* and 'nonpersonal' nouns which are referred to by *which*, and singular personal pronouns distinguish between 'masculine' nouns (referred to by *he*), 'feminine' nouns (referred to by *she*), and 'neuter' nouns (referred to by *it*). The distinction between 'personal' and 'nonpersonal' is not quite the same as that between 'human' and 'nonhuman,' since familiar animals such as pets can be referred to by *who*, and unfamiliar babies can

be referred to by *which*. Nor is it the same as the distinction between 'animate' and 'inanimate,' since both animate nouns like *sheep* and inanimate nouns like *box* are referred to by *which*.

This then gives essentially the following gender classes in English:

(a) personal masculine nouns (who/he): *uncle*
(b) personal feminine nouns (who/she): *aunt*
(c) nonpersonal neuter nouns (which/it): *box*
(d) nonpersonal feminine nouns (which/she): *ship*

Some nouns belong to more than one class. For example, *doctor* can be both personal masculine and personal feminine; *ship* can be nonpersonal neuter as well as nonpersonal feminine. In the plural, the distinction between masculine, feminine, and neuter is neutralized (the personal pronoun is always *they*, and the only gender distinction which is preserved is between 'personal' and 'nonpersonal').

In some languages, meaning alone suffices to determine distinctions of gender (English is basically of this type). In other languages, however, information about the form of the noun (e.g., declension class, phonological form) is also required. In Russian, for example, nouns fall into a few major declensional classes, each of which is associated with a particular gender: *dom* (first declension) 'house' is masculine, *ruka* (second declension) 'arm, hand' is feminine, *skorost* (third declension) 'speed' is feminine, and *okno* (fourth declension) 'window' is neuter. This may lead, as with number, to discrepancies between grammatical and semantic characteristics of particular nouns. For example, the Russian noun *djadja* 'uncle' belongs to the second declension class, but in this case the semantic characteristic takes precedence and agreeing forms are invariably masculine (e.g., *moj djadja* (my-masculine uncle) 'my uncle'). The noun *vrač* 'doctor' belongs to the first declension, but when referring to a female doctor may be used with either masculine or feminine agreeing forms. In this case, feminine agreeing forms are more likely with pronouns and predicates than with noun-phrase modifiers like adjectives (Corbett, 1991). The similarity with the number agreement of collective nouns in English is striking, since here, too, semantic agreement is found with pronouns and predicates.

Noun-Phrase Modifiers

Noun phrases are traditionally thought of as consisting minimally of a head noun, together with any number of noun-phrase modifiers. Typical noun-phrase modifiers are determiners, quantifiers and quantifier phrases, adjectives and adjective phrases, nouns and noun phrases, adpositions and adpositional phrases, and clauses.

Determiners

Determiners form a closed class of functional words which have the general property of not themselves permitting modification. The class of determiners includes articles, personal determiners, demonstratives, interrogative determiners, exclamatory determiners, and quality determiners.

Articles Articles have the function of simply indicating definite or indefinite reference, without containing any identification within themselves of the place where the referent(s) can be located. The English articles are definite *the* and indefinite *a* or *some*. In indefinite reference, *a* is used with singular count nouns, and *some* with noncount and/or plural nouns. Examples are: ***the** film, **the** butter, **the** films, **a** film, **some** butter, **some** films*. Many languages lack articles altogether (e.g., Russian, Lithuanian).

Personal Determiners Personal determiners are determiners which indicate the person of a noun phrase. In English, the personal determiners are *we* and *you* (plural), which can cooccur with grammatically plural common nouns. Examples are: ***we** students*, ***you** students*. Nama (see Person) has both singular and plural first- and second-person determiners. Since personal determiners invariably seem to indicate definiteness, it might be argued that they are simply first- and second-person forms of the definite article. However, the definite article in English does not necessarily imply third-person reference: for example, in an appositional construction like *we, the students*, the first-person personal determiner and the definite article can cooccur. It seems better to treat the usual interpretation of third-person reference induced by the definite article as an implicature which can be canceled if the context requires it.

Demonstratives Demonstratives serve generally to indicate the location of the intended referent(s) of the noun phrase with respect to the context of utterance. English demonstratives are *this/these* and *that/those*, which cooccur with common nouns and have a distinction of grammatical number. Examples are: ***this** box*, ***these** boxes*, ***that** box*, ***those** boxes*. The distinction between *this/these* and *that/those* is one of closeness to and distance from the speaker. In some languages, further distinctions based on closeness to and distance from the hearer can also be found, as well as more recondite distinctions based on visibility

and topological factors such as 'uphill' and 'downhill,' 'upriver' and 'downriver.' For example, Dyirbal (Australia) has basic forms *giyi* (meaning that the referent is visible and here), *bayi* (meaning that the referent is visible and there), and *ŋayi* (meaning that the referent is not visible). To any basic form can be suffixed one of a set of twelve morphemes indicating distance uphill or downhill, distance upriver or downriver, and/or one of a set of three morphemes indicating 'up' (vertically), 'down' (vertically), or 'out in front' (with respect to which way either speaker or hearer is facing; Dixon, 1972). It should be noted that demonstratives may indicate definiteness, as in English, or may be neutral with respect to definiteness, as in Dyirbal.

Interrogative Determiners Interrogative determiners are forms like *which* and *what* in English. Examples are: ***which*** *box?*, ***what*** *box?*

Exclamatory Determiners Exclamatory determiners are forms like *what* in English. Examples are: ***what*** *a fool*!, ***what*** *fools*! Note that the exclamatory determiner *what*, unlike the interrogative determiner *what*, must cooccur with the indefinite determiner *a* when determining a singular count noun.

Quality Determiners Quality determiners are forms like *such* in English. Examples are: ***such*** *a fool*, ***such*** *fools*. Like the exclamatory determiner *what*, this form requires the indefinite determiner *a* when determining a singular count noun.

Quantifiers and Quantifier Phrases

Quantifiers have the general function of indicating the quantity of elements referred to by the noun phrase. Unlike determiners, they permit various kinds of modification and therefore have their own phrasal structure.

In many cases, quantifiers permit the same kinds of modification as adjectives, and might therefore be treated as a special subclass of adjectives. The quantifier *many* in English, for example, permits premodification by the adverb *very* (e.g., ***very many*** *boxes*), and has comparative and superlative forms (***more*** *boxes*, ***most*** *boxes*).

Typical quantifiers in English are: *all, both, half, every, each, any, either, some, much, enough, several, many* (*more, most*), *a few, few* (*fewer, fewest*), *a little, little* (*less, least*), *neither, no*, together with the cardinal numerals *one, two, three*, etc. Examples are: ***all*** *the boxes*, ***enough*** *boxes*, ***few*** *boxes*, ***no*** *boxes*, ***two*** *boxes*. With modification of the quantifier, it is possible to form quantifier phrases: ***virtually all*** *the boxes*, ***not nearly enough*** *boxes*, ***indescribably few*** *boxes*, ***absolutely no*** *boxes*, ***almost two*** *boxes*.

Adjectives and Adjective Phrases

Adjectives and adjective phrases are noun-phrase modifiers par excellence. As well as general adjectives like *red, large, round*, and *brave*, the class of adjectives in English includes ordinal numerals such as *first* and *second*, related adjectives such as *next* and *last*, adjectives such as *same* and *other*, and arguably the whole class of quantifiers (see Determiners).

In some languages, the class of adjectives may be extended to include possessive adjectives, for example, Italian *mia* in *la mia casa* (the my-feminine singular house-feminine singular) 'my house,' and in others, according to Dixon (1977), it may be severely reduced or nonexistent (the concepts being expressed by forms which can be classified as nouns or verbs).

Adjectives in English are generally positioned between determiners and the head noun, for example, *that* ***first brave*** *attempt, a* ***large red*** *apple*. While there is a certain natural ordering relationship between the adjectives themselves, orders which deviate from this ordering are typically possible: *that* ***brave first*** *attempt, a* ***red large*** *apple*. Even quantifiers, which in English typically occupy positions close to (or in complementary distribution with) the determiners, may occur in differing orders with ordinary adjectives: *those* ***two first brave*** *attempts*, *those* ***first two brave*** *attempts*, *those* ***brave two first*** *attempts*.

Adjective phrases in English may be formed by premodification of the adjective by adverbs, or postmodification by prepositional phrases and clauses: ***very*** *proud*, *proud* ***of her achievements***, proud ***that she had won so easily.*** The type of modification has an influence on the order of noun head and adjective-phrase modifier within the noun phrase. Only premodified adjective phrases pattern with single adjectives in occurring before the head noun: *a* ***very proud*** *woman*. Postmodified adjective phrases must occur after the head: *a woman* ***proud of her achievements,*** *a woman* ***proud that she had won so easily.***

Nouns and Noun Phrases

Nouns themselves may act as noun-phrase premodifiers. For example, it can be argued that, in English noun phrases like *a* ***plastic*** *factory*, the item *plastic* is a noun rather than an adjective. The evidence for this is that *plastic* can itself be modified by an adjective such as *corrugated* to give *a* ***corrugated plastic*** *factory* (= a factory which makes corrugated plastic). Adjectives themselves do not permit modification by

adjectives, so there is no alternative but to consider *plastic* as a noun.

It should be noted that noun-phrase modifiers of this type cannot contain determiners, although they may contain quantifiers: *a **party** committee*, **a **that party** committee, a **two-party** committee, an **all-party** committee*.

Adpositions and Adpositional Phrases

Adpositions are prepositions or postpositions, typically taking noun-phrase complements. Prepositional phrases are a common form of noun-phrase postmodifier in English: *the man **on the roof**, a box **without a lid**, the room **underneath the eaves***. Some prepositions can occur alone as postmodifiers: *the room **underneath***.

On the other hand, postpositional phrases in English with the 'genitive' postposition -'*s* are premodifiers with a variety of functions including the possessor function (***the king's** crown*), the subject function (***the king's** decree that windows should be taxed*), the object function (***the king's** execution*), and the descriptive function (*a **women's** hall of residence*).

Phrases of the first three types in English induce the so-called 'definiteness' effect, that is, ***the king's** crown* means '**the** unique crown belonging to the king,' and not '**a** crown belonging to the king.' In order to express the indefinite meaning, the 'double genitive' is used in which the preposition *of* governs a postpositional phrase with -'*s: a crown **of the king's***.

While phrases of the first three types are in complementary distribution in English with the determiners (i.e., ***Edward's** richly jewelled crown* and not **that **Edward's** richly jewelled crown*), this is not universally the case. In Finnish, for example, the premodifying possessor and demonstrative are compatible: *nuo **Aimon** koirat* (those Aimo-genitive dogs) 'those dogs of Aimo's.' There therefore seems to be no general basis for considering premodifying possessor, subject, and object phrases as themselves 'determiners.'

Descriptive 'genitive' phrases of the fourth type have an entirely different distribution. They are compatible with all the determiners and typically occur close to the head noun, after any adjective phrases: *a very pleasant **women's** hall of residence*.

Clauses

Clause modifiers can be divided into two major types: relative clauses, and complement clauses.

Examples of relative clauses in English are:

(a) the Eskimos, *who* *live in igloos*
(b) the Eskimos *who* *live in igloos*
the Eskimos *that* *live in igloos*
(c) the Eskimos *who(m)* *you met*
the Eskimos *that* *you met*
the Eskimos ø *you met*

The relative clause *who live in igloos* in (a) is 'nonrestrictive,' in that it provides additional information about the referents of a noun phrase, *the Eskimos*, whose identity has already been established. By contrast, the relative clauses in (b) and (c) are 'restrictive,' in that the information contained in the relative clause serves to restrict the intended referents to those who satisfy the condition expressed in the relative clause. For example, the relative clauses in (b) restrict the reference to a subset of the set of Eskimos, those who happen to live in igloos.

Nonrestrictive relative clauses in English always begin with a '*wh*-phrase' containing a '*wh*-word' like *who* or *which*. Restrictive clauses may, however, begin with a wh-phrase, or the subordinating conjunction *that*, or zero (symbolized by ø). Zero, however, is not permitted when the 'position relativized' (the position in the relative clause which represents the role played by the intended referents) is the subject position as in (b), rather than the object position as in (c).

The relative clauses in (a), (b), and (c) are based on the finite verb forms *live* and *met*. However, in many languages, relative clauses are essentially based on nonfinite verb forms, for example, Turkish ***John 'un Mary-ye ver-diğ-i** patates* (John-genitive Mary-dative give-participle-his potato) 'the potato John gave to Mary' (Keenan, 1975). Here, the position relativized is the object position. Such relative clauses may be called 'participial' relative clauses. The closest English equivalents are clauses like *living in igloos* in the noun phrase *all Eskimos **living in igloos***. However, in English participial relative clauses, the position relativized is restricted to the subject position, and a full finite relative clause must be used when the position relativized is the object or any other sentential function.

Complement clauses, unlike relative clauses, do not contain a position relativized. Rather, the clause represents the propositional content of a thought or utterance expressed by abstract nouns like *belief, statement, rumour*, etc. Examples are: *the belief **that linguistics is easy**, the statement **that the pound would not be devalued**, the rumour **that the prime minister would resign***.

Noun-Phrase Structure

Configurational versus Appositional Structures

There is considerable evidence that the structure of noun phrases in English is configurational, that is,

Figure 1 Q = Quantifier, D = Determiner, A = Adjective, PP = Postpositional or Prepositional Phrase, N = Noun, S = Relative Clause.

that the structure of a noun phrase like *all those five pleasant women's halls of residence which are described in the University prospectus* can be described by a hierarchical constituent structure as in Figure 1. For example, to give just one argument for one aspect of the structure in Figure 1, the circled node can act as the shared node in 'shared constituent coordination': *all those five – and all these three – **pleasant women's halls of residence which are described in the University prospectus***.

By contrast, the structure of noun phrases in many languages can clearly be appositional, with little or no hierarchical structure. In Nama, for example, a noun phrase like [≠*kini*]-*di* [*ne !nona*]-*di* [*!Gombates di*]-*di* ([book]-third person feminine plural [these three]-third person feminine plural [!Gombate of]-third person feminine plural) 'these three books of !Gombate's' can be considered as consisting of three miniature noun phrases in apposition, each marked as third person feminine plural by the postposition of -*di* and each capable of occurring in isolation. The flavor of the construction is captured by an English version like: *books, these three, the ones of !Gombate*. The whole construction, however, forms a single phrase to which a case-assigning postposition may be attached (Figure 2).

In Nama, an alternative method of constructing noun phrases is hierarchical, and in this case the modifiers are always unmarked for person, number, and gender, and always precede rather than follow the head noun. A similar distinction between 'fractured' and 'nonfractured' phrases has been reported in the Australian language Gooniyandi (McGregor, 1989). In Gooniyandi, however, the elements of a fractured phrase are each independently marked for case, and while they may form a single appositional

Figure 2

unit, they may also be split and placed in different clause positions according to principles of informational structure.

The X-bar Framework

One very influential framework for labeling the constituent structures of hierarchical noun phrases is the X-bar framework introduced by Chomsky (1970) in order to capture the kind of similarity between the structure of sentences and noun phrases which is seen most clearly in nominalization, the formation of nouns from verbs. According to Chomsky, the noun phrase ***Euclid's** proof **of the theorem*** is similar in structure to the sentence ***Euclid** proved **the theorem***: like the verb *prove*, the noun *proof* takes a subject (*Euclid*) and a complement (*the theorem*), the main differences between the two structures (the introduction of the adpositions -*'s* and *of*) being related to the choice of a nominal rather than a verbal head.

In one early version of the X-bar theory (see Jackendoff, 1977 for discussion), the verb is taken to be the head of a sentence, and the parallel between sentence and noun phrase emerges very clearly (Figure 3). The maximal (phrasal) level of any category is taken to be X″ (where X represents any word-level category N(oun), V(erb), P(reposition), or A(djective)). N″ is therefore equivalent to noun phrase, P″ to prepositional phrase, A″ to adjectival phrase, and V″ is equivalent to sentence. Complements are placed as sisters of an intermediate level node X′, and subjects (treated invariantly as N″ despite the presence of the adposition-*'s* in the noun phrase subject) are placed in the so-called 'specifier' position as daughters of N″ or V″. The parallelism is however spoilt in this early version only by the presence of a tense node T in the sentence, and the fact that in noun phrases the specifier position may be occupied by a determiner node D, capturing the complementary distribution between -*'s* genitive phrases and determiners which holds in English (Figure 4).

In the model of the noun phrase expressed by Figures 3 and 4, the N′ node is recursive and permits

Figure 3

Figure 4

Figure 5

the addition of any number of additional modifiers such as adjective phrases, prepositional phrases, and relative clauses. A noun phrase such as *those difficult proofs of the theorem from Euclid which are set out in our textbook* would have the structure in Figure 5.

Structures like Figure 5 seem fairly successful in capturing the structure of complex noun phrases. However, there are some potential problems. First, there are elements which occur higher in the structure and do not seem to be well catered for: for example, the quantifiers *all, both*, and *half*, which in English can precede the definite determiners (***all** the boxes*), and genitive phrases in languages (e.g., Finnish and Hungarian) which allow the genitive phrase to precede the determiner rather than occur in complementary distribution with it. Second, the distinction between complements and other kinds of modifier seems related to the noun's ability to assign a 'semantic' (or 'thematic') role to the complement, but it is not clear that this entails the existence of a different 'syntactic' structure for complements involving the existence of a distinct N′ node (for example, the tendency of complements to occur closer to the noun than other modifiers could be explained by a principle such as the domain adjacency condition of Travis (1984), which requires elements assigned a thematic role by a head to be adjacent to that head).

These issues remain to be developed thoroughly. One possible direction in which solutions might lie is in abandoning bar structures altogether and treating all modifiers as sisters of a single recursive node with no distinctions of bar level (a move proposed in principle by, for example, Speas, 1990). In the case of noun phrases, the single node would be the node N, and all modifiers, without exception, would be sisters of N.

Further independent principles would then be required to account for the possible orders in which modifiers can occur. Work on the typology of noun phrases has begun to show, however, that the relative order of some basic types of premodifiers is extremely stable across the world's languages, the order being: demonstrative – numeral – adjective – head noun (see Rijkhoff, 1992). This suggests that, at least for these categories of modifier when they precede the head, very general principles governing the relative application of modifiers are involved.

The DP Hypothesis

Discussions of noun-phrase structure which maintain the noun as the head of the noun phrase have been overshadowed by the DP (determiner phrase) hypothesis, which maintains that determiners are the ultimate heads (Abney, 1987). A survey of the development of the DP hypothesis may be found in Ouhalla (1991: ch. 4).

A typical DP structure for the noun phrase *the proof of the theorem* is Figure 6 Instead of being

Figure 6

Figure 7 *t* is the trace of the D″ *Euclid* after movement from specifier position in N″, and *e* is the empty D node.

a modifier, the determiner *the* is the head of the construction, taking an N″ *proof of the theorem* as its complement. In a noun phrase like *Euclid's proof of the theorem*, the specifier positions of N″ and D″ can both be exploited by assuming that *Euclid* originates in the specifier position of N″, where it can be assigned the appropriate thematic role (agent) by the noun. *Euclid* can then move to the specifier position of D″, where it is assigned the genitive case (surfacing as the -'*s* postposition) by the empty element D Figure 7.

This structure, in which the subject and object of the noun are originally both within N″ and movement of the subject from within N″ up to the specifier position of a nominal 'functional' category D, then parallels an analysis of sentences in which the subject and object of the verb are originally both within V″ and movement of the subject places the subject in the specifier position of a sentential 'functional' category I (which contains information about the tense and agreement properties of the sentence). The parallelism between noun phrase and sentence originally sought by the X-bar theory is then complete (see Figure 8).

Work in the DP hypothesis has sought to refine the analysis of the functional categories in the noun phrase by including D (determiner) and AGR (agreement) as heads, paralleling the separation of I into T (tense) and AGR (agreement) in the analysis of sentences. This may account for noun phrases in which nouns have markers of agreement with their genitive phrases (e.g., Turkish *şu benim şapka-m* (this my hat-first person singular) 'this my hat.'

In addition, the node K (case) has been proposed as the highest functional head in noun phrases which are marked for case, reflecting the idea that case determines the external distribution of noun phrases. Cased noun phrases are then KP rather than DP or NP. It can be predicted that, parallel to the further refinement of functional categories within

Figure 8 *t* is the trace of the D″ *Euclid* after movement from specifier position in V″, and *e* is the empty I node.

the sentence (for example, the inclusion of aspect and negation), further functional categories will emerge within the noun phrase.

While the DP hypothesis looks attractive, it too has a number of problems (see Payne, 1993 for discussion). For example, an analysis of the noun phrase in which there is a skeleton of N nodes from the phrasal to the lexical level naturally accounts for the percolation along this skeleton of morphological agreement features (e.g., case, number, gender, definiteness) in languages like Russian, in which nearly all noun phrase constituents are morphologically marked. In Figure 9, for example, the features of instrumental case and plural number percolate to every constituent of the noun phrase.

If, however, categories like case and definiteness are represented by single individual nodes K and D, and these are the highest nodes in constituency structure trees under the DP hypothesis, the natural prediction is that only the highest nodes in the tree will be morphologically marked for those categories.

Nouns

M Koptjevskaja-Tamm, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Prototypical nouns refer to things, persons, places, and other more or less concrete objects, but the noun class itself normally includes many more items. Nouns always constitute an open class, even in languages that have relatively few nouns compared with the European languages, such as Iroquoian languages (Mithun, 2000). Languages have normally multiple ways of deriving nouns, both from other word classes by means of nominalization (*see* **Nominalization**) and from other nouns. Nouns or their different forms can develop into words of other classes, e.g., adverbs and adpositions. Nouns seem to exist as a distinct word class in most languages, even though languages vary as to how pronounced their noun–verb distinction is (Evans, 2000; also *see* **Word Classes/Parts of Speech: Overview**).

Nominal Subcategories

Nouns can be classified in various ways. It has become usual in linguistic literature to order nouns according to one or another version of what has been termed the animacy hierarchy or the topicality hierarchy (Comrie, 1981: 178–193), the hierarchy of individuation (Sasse, 1993), or the empathy hierarchy (Kuno and Kaburaki, 1977; Lehmann and Moravcsik, 2000). The basic idea is that these hierarchies reflect speakers' different degrees of empathy with different types of entities and their different needs and/or abilities

Nouns

M Koptjevskaja-Tamm, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Prototypical nouns refer to things, persons, places, and other more or less concrete objects, but the noun class itself normally includes many more items. Nouns always constitute an open class, even in languages that have relatively few nouns compared with the European languages, such as Iroquoian languages (Mithun, 2000). Languages have normally multiple ways of deriving nouns, both from other word classes by means of nominalization (*see* **Nominalization**) and from other nouns. Nouns or their different forms can develop into words of other classes, e.g., adverbs and adpositions. Nouns seem to exist as a distinct word class in most languages, even though languages vary as to how pronounced their noun–verb distinction is (Evans, 2000; also *see* **Word Classes/Parts of Speech: Overview**).

Nominal Subcategories

Nouns can be classified in various ways. It has become usual in linguistic literature to order nouns according to one or another version of what has been termed the animacy hierarchy or the topicality hierarchy (Comrie, 1981: 178–193), the hierarchy of individuation (Sasse, 1993), or the empathy hierarchy (Kuno and Kaburaki, 1977; Lehmann and Moravcsik, 2000). The basic idea is that these hierarchies reflect speakers' different degrees of empathy with different types of entities and their different needs and/or abilities

to perceive those as individuals. The common part in all of them is the basic distinction humans – other animates – inanimate entities. The highest (left) part of the proposed hierarchies differs; thus, an additional split may single out personal proper names and occasionally certain kin terms. The highest positions belong to pronouns for speech-act participants (first- and second-person pronouns), i.e., not nouns. Actually, opinions and descriptive praxis vary on whether (personal) proper names should be considered a subclass of nouns or a category of their own. Thus, they often have inflectional and distributional peculiarities stemming from their inherent uniqueness and definiteness, e.g., resistance to pluralization and noncompatibility with usual articles. In a number of languages, personal proper names require special proprial articles, distinct from those used with normal nouns.

The lower part of the hierarchies differs even more substantially among the different scholars. Thus, abstract nouns, such as *love*, *beauty*, or *democracy*, are opposed to all the others, concrete nouns and are clearly lower in their degree of individuation. The same goes for words denoting substances (prototypical mass nouns), such as *air* or *water*, compared with words denoting individual objects (prototypical count nouns), e.g., *girl*, *cat*, and *cup*. However, these two distinctions are rather orthogonal to each other (for a different opinion, see Sasse, 1993).

Various structural phenomena and grammatical rules across languages are in one way or another sensitive to the animacy/empathy/individuation hierarchy, e.g., the distribution of number distinctions (*see* **Number**), the number of case distinctions (*see* **Case**), direct versus inverse marking of subject–object relations (e.g., in Navajo), etc., (see Dahl and Fraurud, 1996 for an overview). However, since the hierarchy looks different for the different phenomena and is often "operationally defined as to whatever determines the phenomena under investigation" (Dahl, 2000: 40), one might suspect that it is in fact an illusion, hiding several different, more basic distinctions. And in fact, the seemingly self-explanatory concept of individuation is itself in need of independent psycholinguistic research (Comrie, 1981: 178–193).

Classifications along the above given lines are sensitive to the type of entity denoted by a noun, i.e., to its correlate in the physical world, the class of its possible referents. However, what often counts even more is the mental reflection of these possible referents, the way they are construed, i.e., the properties of the corresponding concepts in the mental lexicon. Take, for instance, the opposition between count and mass nouns. In English, the count noun *cow* easily combines with numerals, e.g., *one cow, three cows,* etc., with the indefinite article *a*, and with the denumerating measure words *many*, *several*, etc. The mass noun *petrol* cannot combine with numerals and with the indefinite article *a*, takes the measure word *much* instead of *many*, and lacks the number opposition otherwise typical of English nouns (cf. *cow* vs. *cows* with *petrol* vs. **petrols*). The underlying semantic difference is often described as the difference between denoting (or referring to) discrete entities with a well-defined shape and precise limits versus homogeneous, undifferentiated stuff without any certain shape or precise limits. The count/mass distinction in languages such as English, French, or Russian shows a strong correlation between the properties of referents and their proneness to be referred to by a count or a mass noun, more or less in accordance with the animacy hierarchy. Thus, humans and animals favor a high degree of individuation and are normally coded by count nouns, but stuffs are more often than not expressed by mass nouns. However, discreteness (boundedness) of count-noun referents and homogeneity of mass-noun referents reflect not so much the objective reality itself, but rather its construals by language speakers. Thus, under appropriate circumstances several cows can alternatively be referred to as *(several) cows*; as *a herd (of cows),* by means of a collective count noun; or as *cattle*, by means of a collective mass noun. There are amazing crosslinguistic differences in the lexical preferences for count or mass uses even within the European Indo-European languages, which deserve profound study; it is also far from clear to what extent the count/mass distinction is useful crosslinguistically (Behrens, 1995; Rijkhoff, 2002: 44–56; Koptjevskaja-Tamm, 2004b). Personal proper names are another example of an ontologically based, rather than phenomenologically based, classification: thus, for example, organizations are often given proper names that may behave linguistically more or less similarly to personal proper names (Fraurud, 1996).

Language-specific classifications of nouns (or of the corresponding entities in our conceptual world) underlie their different combinability with various linguistic elements. The most grammaticalized form of nominal classification is gender (*see* **Gender, Grammatical**). Several properties distinguish prototypical genders from prototypical classifiers: numeral classifiers, occurring in numeral constructions, e.g., in many Southeast Asian languages (*see* **Numerals**), or possessive classifiers, occurring in adnominal possession, e.g., in Melanesian languages (*see* **Possession, Adnominal; Classifiers and Noun Classes: Semantics**). There are, however, many intermediate cases (cf. Aikhenvald, 2000; Rijkhoff, 2002).

Relationality

While almost all verbs are relational in the sense of relating participants to an event (*see* **Verbs**), most prototypical nouns are absolute, or 'sortal' (Löbner, 1985): they designate concrete individual objects, e.g., a cup or a book, not obviously related to other entities. A lot of nouns are relational – for example, body-part nouns and nouns referring to other parts, kin terms and nouns referring to other interpersonal relations, or words like *consequence* or *results*. They invoke a special relation to another entity and can often not be understood without this entity: a person cannot be a neighbor or a son, but is always someone's neighbor or son. Many more nouns are relational in a weak sense, in that their meaning itself presupposes or invokes specific relations. Thus, for example, since books are strongly associated with their authors, with their content, and with a specific purpose, the corresponding relations are readily invoked by the semantic structure of the word *book*. The term 'qualia structure' (Pustejovsky, 1998) refers to a system of relations that characterize the semantics of nominals, in a way parallel to the argument structure of a verb, and includes the four basic roles: (1) the constitutive role (the relation between an object and its constituents, or proper parts), (2) the formal role, distinguishing the object within a larger domain (color, shape, etc.), (3) the telic role (purpose and function of the object), and (4) the agentive role (factors involved in the origin or 'bringing about' of an object).

There has been relatively much crosslinguistic research on the issues of inalienable versus alienable possession (*see* **Possession, Adnominal**), or how typically body-part terms and/or kin terms are singled out in the ways their relations to other entities are encoded. Otherwise, the nominal qualia structure has received very little attention compared with the extensive work on the verbal argument structure and its manifestations across languages. There are, however, many interesting issues and amazing crosslinguistic variation here. Thus, for example, Russian and Swedish mark the telic role of 'key' in different, not to say opposite, ways: 'the key that belongs to the door, i.e., the key the purpose of which is to open the door' corresponds to *nyckeln* TILL *dörren*, 'key.the TO door.the,' in Swedish, but to *ключ* OT *dveri*, 'key FROM door:GEN,' in Russian.

Nominal Inflectional Morphology and Functions

Nouns typically head noun phrases that are used for reference, i.e., as arguments and adjuncts to predicates (e.g., *The little* ***boy*** *is playing with the new* ***toy***) or as attributes to other nouns (the **boy's** *new toy*). They can also be used in nonreferring functions, e.g., as predicates (*Peter is a* ***boy***), and as nonreferential attributes, e.g., *a children's hospital*. In these functions nouns often show fewer of their typical inflectional properties and sometimes even acquire certain properties of other word classes (Hopper and Thompson, 1984; Stassen, 1997; Croft, 2001; Mauri, 2003; Koptjevskaja-Tamm, 2004, and **Nonverbal Predication**).

Typical nominal inflectional markers include markers of number (*see* **Number**), case (*see* **Case**), possession (*see* **Possession, Adnominal**), and definiteness (*see* **Definite and Indefinite**). The noun in (1), from Hungarian, carries the plural number marker, the third person plural possessive marker, and the accusative case marker, while the above-mentioned Swedish example demonstrates inflection for definiteness.

(1) barát-ai-k-at
friend-PL-POSS.3PL-ACC
'their friends (ACC)'

Both case markers and possessive markers usually signal syntactic relations between nouns (or noun phrases headed by them) and other expressions and thus constitute nominal dependent marking and head marking, respectively (Nichols, 1986). Possessive markers are normally chosen in accordance with the person and number of the possessor, that is either explicitly mentioned in the same construction or not. In many languages nouns can also attach person markers when used as nominal predicates. Example (2), from Chukchi (Chukot), illustrates a polite introduction routine.

(2) qun = waj enmen Cəkwaŋaqaj-eɣəm
INTERJ = INTERJ so personal.name-1SG.ABS
[Cəkwaŋaqaj:] 'Well, then I'm Cəkwaŋaqaj.'
eej Cəkwaŋaqaj-eɣət
INTJ personal.name-2SG.ABS
[The woman:] 'Ooh, you're
Cəkwaŋaqaj.' (Dunn, 1999: 318)

As predicates, nouns can sometimes attach tense-aspect-mood markers. However, even nouns used in other functions – as arguments and adjuncts – can occasionally inflect for these categories, independently of the clause they belong to, as in (3) from Guaraní.

(3) O-va-ta che-róga-kue-pe.
3-move-FUT 1SG-house-PST-in
'He will move into my former house.'
(Nordlinger and Sadler, 2004: 781)

All of the categories expressed by nominal inflectional morphology can also be expressed by other means, such as grammatical words, and the different

categories differ in their crosslinguistic proneness to be encoded by inflection. Thus, while case is a relatively common inflectional category, bound definiteness markers are much more rare.

Languages also differ considerably in whether they have nominal inflectional morphology at all (and how much). It has been suggested (Lehmann and Moravcsik, 2000; Moravcsik, 2003) that nominal inflection in a language implies verbal inflection. Thus, while there are languages with both, with neither (Vietnamese), and with only verbal but no nominal inflection (Japanese), nominal inflection without verbal does not yet seem to have been attested. There are other crosslinguistic generalizations relating nominal and verbal morphology. For example, according to Nichols (1986: 75), "If a language has major, salient head-marking morphology anywhere, it will have it at the clause level," or in other words, if a language uses head-marking in possessive noun phrases (primarily possessive affixes), it will use head-marking to relate arguments to verbs (i.e., primarily verbal agreement markers). Siewierska (1998) confirms further that the majority of languages in her large global sample show close similarity between nominal possessive affixes and verbal person marking.

There are also possible generalizations on interaction among different nominal inflectional categories. According to Aikhenvald and Dixon (1998) and Corbett (2000), there are many examples of case systems with a larger number of distinctions in the singular than in the plural, but no examples are given of the opposite possibility. In Basque, number distinctions hit only definite nouns. In other languages definite nominals sometimes show more elaborate case and/or number paradigms than indefinite ones even though languages with both case and bound definiteness markers are relatively rare: Matthew Dryer's 700-language sample contains only 25 instances (Matthew Dryer, personal communication).

The order of nominal inflectional (and derivational) markers with respect to the stem and to each other obeys certain principles, basically reflecting the degree of semantic relevance of the corresponding categories to the meaning of the stem (Bybee, 1985). However, languages sometimes show 'contradictory' orders between inflectional markers. Thus, while in (1) from Hungarian, the possessive suffix precedes the case suffix, Finnish nouns show the opposite order in their nominal suffixes.

Number

G G Corbett, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

Number is one of the most common features of the world's languages. While it is common, it is certainly not uniform. The situation in languages like English is often treated as normal. Yet the number feature reveals many surprises, and the system found in English is a rather extreme one, when seen against the possibilities established from a survey of the languages of the world. We shall consider characteristics of the English-type systems in turn, showing some of the ways in which they are typical or atypical and the contrasting types of system found elsewhere. We shall give particular prominence to the question of number values. This entry is based on Corbett (2000), where a much fuller account is given.

Nominal and Verbal Number

English makes a semantic and a formal distinction between, for instance, *cat* and *cats*, *child* and *children*. In English, this number distinction reflects a nominal feature. It is realized on nouns via relatively simple inflectional morphology. (There are many languages with more complex morphological realization of number, see, for instance, the account of Nilo-Saharan languages in Dimmendaal, 2000.) In English, when the number feature is realized on verbs, this is by agreement with a subject noun phrase, as in *the children were playing together*. The verb is plural to indicate the number of children, and not the number of playing events. That is, we have a nominal feature which can be realized where expected, on the noun phrase, and also on the verb. While there are many languages like English in this respect, we also find instances of verbal number, that is, where number is realized on the verb to indicate the number of events or the number of participants. For an example we turn to Rapanui (an Oceanic language spoken on Easter Island) (Veronica Du Feu, personal communication):

(1) ruku
'dive'

(2) ruku ruku
'go diving'

The form in (2) is appropriate if there is more than one dive; it does not require more than one person to be diving. The reduplicated form indicates verbal plurality: there are plural events. Verbal number may also be concerned with the number of participants rather than the number of events (see, for instance, Durie, 1986). Verbal number may be restricted to relatively small numbers of verbs, and it rarely shows more than a two-way opposition (for details see Corbett, 2000: 243–264). Nominal number shows a greater range of possibilities and we shall concentrate on that type.

Number as an Obligatory Category

Number is an obligatory category in English. If someone says *there's a goat in the garden* when there are several, this is misleading and inappropriate. In many languages, however, the use of the plural is not obligatory, but it is available when it is important to mark number. Perhaps the clearest example is provided by the Cushitic language Baiso, spoken on Gidicho Island in Lake Abaya (southern Ethiopia) and on the western shore of the lake. Baiso nouns can mark 'general' meaning, that is, they have a form which

Number is one of the most common features of the world's languages. While it is common, it is certainly not uniform. The situation in languages like English is often treated as normal. Yet the number feature reveals many surprises, and the system found in English is a rather extreme one, when seen against the possibilities established from a survey of the languages of the world. We shall consider characteristics of the English-type systems in turn, showing some of the ways in which they are typical or atypical and the contrasting types of system found elsewhere. We shall give particular prominence to the question of number values. This entry is based on Corbett (2000), where a much fuller account is given.

Nominal and Verbal Number

English makes a semantic and a formal distinction between, for instance, *cat* and *cats*, *child* and *children*. In English, this number distinction reflects a nominal feature. It is realized on nouns via relatively simple inflectional morphology. (There are many languages with more complex morphological realization of number, see, for instance, the account of Nilo-Saharan languages in Dimmendaal, 2000.) In English, when the number feature is realized on verbs, this is by agreement with a subject noun phrase, as in *the children were playing together*. The verb is plural to indicate the number of children, and not the number of playing events. That is, we have a nominal feature which can be realized where expected, on the noun phrase, and also on the verb. While there are many languages like English in this respect, we also find instances of verbal number, that is, where number is realized on the verb to indicate the number of events or the number of participants. For an example we turn to Rapanui (an Oceanic language spoken on Easter Island) (Veronica Du Feu, personal communication):

(1) ruku
'dive'

(2) ruku ruku
'go diving'

The form in (2) is appropriate if there is more than one dive; it does not require more than one person to be diving. The reduplicated form indicates verbal plurality: there are plural events. Verbal number may also be concerned with the number of participants rather than the number of events (see, for instance, Durie, 1986). Verbal number may be restricted to relatively small numbers of verbs, and it rarely shows more than a two-way opposition (for details see Corbett, 2000: 243–264). Nominal number shows a greater range of possibilities and we shall concentrate on that type.

Number as an Obligatory Category

Number is an obligatory category in English. If someone says *there's a goat in the garden* when there are several, this is misleading and inappropriate. In many languages, however, the use of the plural is not obligatory, but it is available when it is important to mark number. Perhaps the clearest example is provided by the Cushitic language Baiso, spoken on Gidicho Island in Lake Abaya (southern Ethiopia) and on the western shore of the lake. Baiso nouns can mark 'general' meaning, that is, they have a form which

is noncommittal as to number, along with singular, paucal (example (8) below), and plural (Corbett and Hayward, 1987). The form *lúban* 'lion' does not specify a number of lions (it could be one, or more than that) (Dick Hayward, personal communication).

(3) lúban foofe
lion.GENERAL watched.1SING
'I watched lion'

Having a distinct form for general number is highly unusual. There are many languages which can express general meaning, but they do so by means of a form shared with the singular. This more usual situation, with general identical to singular, can be illustrated from Arbore (also a Cushitic language). We find pairs like the following (Hayward, 1984: 159–183).

(4) a. keléh
'gelded goat(s)'
b. keleh-mé
'gelded goats'
c. goran
'heifer cow(s)'
d. gor-nó
'heifer cows'
e. kér
'dog(s)'
f. ker-ó
'dogs'

Alhough the morphology may appear comparable to English, the meanings of the forms are different: *keró* guarantees more than one dog, and it would be used when to indicate this is important; *kér* does not imply only one: it might be one, it might be more than that. (There are other, less frequent number pairings in Arbore.) Systems like that of Arbore, in which number is not an obligatory category (and so is arguably not inflectional) are common in the world's languages. At the opposite extreme from English we find Pirahã, the only remaining member of the Mura family, spoken in 1997 by some 220 people along the Maici River (Amazonas, Brazil). It has been described by Everett (1986), who stated that it had no system of grammatical number, even in the pronouns. This is extremely rare.

The Nominals Involved in the Number System

In English and similar languages, the majority of nominals can mark number, from the personal pronouns and nouns denoting persons (e.g., *nurse*) down to those denoting inanimate objects (e.g., *blanket*), and even to some denoting abstracts (e.g., *week*). Many languages restrict the number opposition to fewer nominals, namely those which are high in animacy. Thus, in Slavey (an Athapaskan language spoken in parts of the Northwest Territories, British Columbia, and Alberta, Canada), number may be marked on the noun phrase, provided the noun denotes a human or a dog (Rice, 1989: 247).

We wish to investigate the countability preferences (Allan, 1980) of nominals (including pronouns as well as nouns). There is considerable variety in the world's languages. Consider the following Warrgamay example (Queensland, Australia) (Dixon, 1980: 266–268):

(5) yibi-yibi ŋulmburu-ŋgu
child-REDUP.ABS woman-ERG
wurrbi-bajun-du buudi-lgani-y
big-very-ERG take-CONT-UNMARKED.TENSE
malan-gu
river-ALL
'the very big woman/women is/are taking the children to the creek'

We see that a noun can be marked for number in Warrgamay, as in *yibi-yibi* 'child.' However, this is not required; forms like *ŋulmburuŋgu* 'woman/women' are quite normal. Dixon (1980: 267) stated that a noun in this language 'is not normally specified for number' and suggested that this is the typical situation in Australia (1980: 22). Warrgamay is particularly interesting, since in (5) the verb does not determine number either. As for pronouns, the first and second persons (singular, dual, and plural) and the third dual and plural are "strictly specified for number and are used only for reference to humans, and occasionally tame dogs (Dixon, 1981: 39–40). The form filling the third singular slot can range over all persons and all numbers (it can have nonhuman as well as human reference) but its "unmarked sense" (1981: 40) is third-person singular.

Thus, in Warrgamay, the word for 'woman' is not normally specified for number, while in English it must be. Yet the first and second persons are. This is part of a wider pattern. The observation that the sets of nominals involved in number distinctions are related to animacy was taken up and investigated further by Smith-Stark (1974), who proposed the version of the animacy hierarchy shown in Figure 1.

Smith-Stark suggested that plurality 'splits' a language if "it is a significant opposition for certain categories but irrelevant for others" (1974: 657). The type of evidence he produced concerned marking of the noun phrase for number (usually by marking on the noun itself) and agreement in number (mainly verbal agreement but with some instances of agreement within the noun phrase).

As postulating a typological hierarchy implies, various languages make the split at different points. An

Speaker > Addressee > Kin > Rational > Human > Animate > Inanimate
(1st-person pronouns) (2nd-person pronouns)

Figure 1 The Smith-Stark (animacy) hierarchy.

example of a split between pronouns and nouns is found in Bengali, since according to Masica (1991: 225–226) number is obligatory for pronouns, while other plural suffixes are optional. In Gunwinggu, a Gunwingguan language of western Arnhem Land, pronominal affixes on the verb mark number for humans but not normally for nonhumans (Evans, 2003: 234–235, 417–418). A lower split is found in agreement in Mundari (a Munda language of east India); verbs agree in number with nominals on the hierarchy as far down as animate nouns, but not with inanimates (Bhattacharya, 1976: 191–192).

Interesting information on which nouns have a plural, and whether its use is obligatory, can be found in Haspelmath's (2005) map for the *World atlas of language structures*. His data, from a sample of 290 languages, are in accord with the animacy hierarchy. In addition, he mapped the distribution of the different types. Obligatory number marking for different types of noun (the 'English pattern') is found in western and northern Eurasia and much of Africa. Elsewhere, Haspelmath's sample reveals a more mixed picture. He found optional marking of number to be common in Southeast and East Asia and Australia, while a lack of number marking is widespread in New Guinea and Australia. For comparable data on pronouns see Daniel (2005).

Even in languages that mark number as extensively as English does, there are usually some nouns which are off the bottom of the scale, those which do not enter into number oppositions. In English, they typically pattern with the singulars, thus *reliability* has the form of a singular and takes singular agreements. On the other hand, in Manam (Lichtenberk, 1983: 269), mass nouns are treated as plural (unless they refer to a single quantity):

(6) daŋ di-éno
water 3PL-exist
'there is water (available)'

In various Bantu languages we often find both possibilities: some mass nouns are singular and some plural.

We have concentrated on the basic singular/plural opposition. An important goal of the typological investigation of number is to integrate the typology of the nominals involved in number with the typology of values (see 'Number Values'). This is a significant challenge. Smith-Stark considered only plurals, suggesting that other values, such as the dual, would follow the plural. This situation is certainly not the only possibility. For instance, in Avar, some nouns have a paucal, and in modern Hebrew and in Maltese, some nouns have a dual (in addition to singular and plural). The nouns involved are relatively few in comparison with those with a plural, and they are not those at the top of the animacy hierarchy. These paucals and duals can be analyzed as 'minor numbers'; they do not pattern according to the animacy hierarchy, but they are counterexamples of a narrowly definable type. Then there are other apparent number values that appear to run counter to the hierarchy; for example, associatives, as in Bagvalal (Nakh-Daghestanian) *jaš* 'girl, daughter,' *jaš-i* (normal plural) 'girls, daughters,' *jaš-āri* (associative plural) 'daughter and her family' (Danièl, 2001: 135–136). Associatives involve an additional category and so fall outside the scope of the constraints above (Corbett and Mithun, 1996; Moravcsik, 2003; Moravcsik and Daniel, 2005). A discussion of these various complications is beyond the scope of this entry; see Corbett (2000: 54–88) for more detailed data on the animacy hierarchy and Corbett (2000: 89–132) for an integration of the typology of the nominals involved in number oppositions with the typology of values.

The Semantics of Number

So long as we stay with innocent examples like English *cat* and *cats,* the semantics of number look clear, since *cats* is appropriate for more than one instance of *cat*. In fact, there are many concealed difficulties: a concise overview of work on number within formal semantics can be found in Link (1998), who showed how the study of plurals related to different movements in linguistic semantics and provided a substantial bibliography. Ordinary plurals like *cats* are only one possible type of number; if we consider *I* versus *we,* it becomes clear that here we have an associative use of the plural; *we* is most often used for 'I and other(s) associated with me' (Moravcsik, 2003; Corbett, 2004). These different uses are bound up with the nominal's position on the animacy hierarchy. Thus, in English, while the items at the very top of the hierarchy have associative

uses, nouns lower on the hierarchy, like *coffee,* have a number opposition provided they are recategorized. If *coffee* denotes a type, or a typical quantity of coffee, then there is an available plural, as in: *she always keeps three different coffees,* and *we've ordered two teas and three coffees.*

Number Values

A striking way in which English is limited in its number system is in terms of the number values. It can distinguish only between singular and plural. Many languages have more distinctions.

The Dual

A common system is one in which singular and plural are supplemented by a dual to refer to two distinct real-world entities. Examples are widespread. We will take Central Yupik, as spoken in southwestern Alaska; the number forms are: singular *arnaq* 'woman,' dual *arnak* 'two women' and plural *arnat* 'three or more women.' The addition of the dual has an effect on the plural, which is now used for three or more real-world entities. More generally, a change in the system gives the plural a different meaning. As with the plural, the use of the dual need not be obligatory; Slovenian is a language with a dual, but one whose use is subject to interesting conditions (see Derganc, 2003). And in Kxoe (Central Khoisan) the plural is used of a man and wife; to use the dual would be an insult, because it would suggest they were together by chance (Treis, 2000).

The Trial

The 'trial' refers to three distinct real-world entities, and it occurs in systems with the number values: singular, dual, trial and plural. A particularly clear instance is found in Larike (Larike–Wakasihu), a Central Moluccan language spoken on the western tip of Ambon Island, Indonesia. (Central Moluccan forms part of the Central Malayo–Polynesian subgroup of Austronesian.) This example is from Laidig and Laidig (1990: 96):

(7) Matidui-tue au-huse nusa
3TRIAL-live at-there island
'those three live on the island over there'

The reason for citing Larike is that it has a 'genuine' trial, which is available for use for exactly three (Laidig and Laidig, 1990: 92). The dual and trial forms of Larike can be traced back to the numerals 'two' and 'three' and the plural comes historically from 'four.' This is a frequent development in Austronesian languages. Accordingly, some linguists use the term 'trial' more widely, according to the form of the inflections (derived historically from the numeral three), even for languages where the forms are used synchronically for small groups, including those greater than three (for which 'paucal' would be more accurate). The trial of Larike is not a paucal, but strictly a trial according to Laidig and Laidig.

The Paucal

As just noted, paucals are used to refer to a small number of distinct real world entities, somewhat akin to the English quantifier 'a few' in meaning. There is no specific upper numerical limit on the use of paucals (and their lower boundary varies according to the system in which they are found). Let us return to the Cushitic language Baiso. Besides the general number forms (as in (3), where number is not specified), nouns also have singular, paucal and plural. Here is the paucal (Dick Hayward, personal communication).

(8) luban-jaa foofe
lion-PAUCAL watched.1SING
'I watched a few lions'

The paucal is used in Baiso when referring to a small number of individuals, from two to about six. The Baiso system (for nouns) of singular/paucal/plural, also with a 'general' form, is rare. The paucal is usually found together with a dual, so that the system of number values is singular/dual/paucal/plural. This widespread system is found, for example, in Manam, an Oceanic language spoken on islands off the north coast of New Guinea (Lichtenberk, 1983: 108–109).

The Largest Systems

It is interesting to ask what is the largest system of number values. There are claims in the literature for languages with a 'quadral,' for four distinct real-world entities, as part of a system of five number values. Systems with five number values have indeed been found, and these are the largest systems, but the evidence specifically for a quadral is less certain. All the claims come from within the Austronesian family, and the best documented case is Sursurunga (Hutchisson, 1986, and personal communications), spoken in southern New Ireland. The forms in question are restricted to the personal pronouns, but are found with all of them, the first person (inclusive and exclusive), the second and the third. Given the conclusion to be reached, we shall label the forms 'greater paucal' (Table 1).

Here is an example of what we shall call a greater paucal form (Hutchisson, 1986; and personal communications).

Table 1 Emphatic pronouns in Sursurunga (Based on Hutchisson, 1986, and personal communications)

	Singular	*Dual*	*Paucal*	*Greater paucal*	*Plural*
1 exclusive	iau	giur	gimtul	gimhat	gim
1 inclusive	—	gitar	gittul	githat	git
2	iáu	gaur	gamtul	gamhat	gam
3	-i/on/ái	diar	ditul	dihat	di

Note that á is used to indicate schwa (ə).

(9) gim-hat 1EXCL-GREATER_PAUCAL káwán maternal.uncle:nephew/niece
'we four who are in an uncle–nephew/niece relationship'

The greater paucal has two further uses. First, Sursurunga plural pronouns are never used with terms for dyads (kinship pairings like uncle–nephew/niece). Here the greater paucal is used, for a minimum of four, and not just for exactly four (Hutchisson, 1986: 10). Second, a speaker may use the first-person-inclusive greater paucal in hortatory discourse to suggest joint action involving more than four persons, including the speaker. These two uses account for the majority of instances of the use of the forms in question. In terms of meaning, the term 'quadral' is therefore not appropriate, and so 'paucal' is more accurate.

Why then have we suggested 'greater paucal'? To see why, we need to examine the rest of the number system of Sursurunga (using data and judgments from Don Hutchisson, personal communications). The regular use of the dual is quite strictly for two people. It also has one special use for the singular when the referent is in a taboo relationship to the speaker. The so-called 'trial' can be used for three, and it can also refer to small groups, typically around three or four, and to nuclear families of any size. It is, therefore, not strictly a trial, as discussed earlier: it could be glossed as 'a few' and it should be labelled 'paucal.' The development of trial into a paucal is a frequent one, as we noted above. The so-called 'quadral,' as we have just seen, is primarily used in different ways with larger groups, of four or more (an appropriate gloss would be 'several'). This too would qualify as a paucal. There are therefore two paucals in Sursurunga, a paucal (traditionally 'trial') and a greater paucal (traditionally 'quadral'). The plural is for numbers of entities larger than what is covered by the greater paucal; however, there is no strict dividing line. Using semantic labels, we can say that the number feature in Sursurunga has the values: singular, dual, paucal, greater paucal, and plural. Thus, Sursurunga has a well-documented five-value number feature. There are certainly other languages with five number values, namely Lihir, Tangga and Marshallese; we do not have such detailed information as for Sursurunga and there is no certain case of a quadral: it seems that in all cases the highest value below plural in such systems can be used as a paucal.

Besides the split in the paucal, we may also find languages that split the plural, with 'greater plurals' of different types, as for instance in Arabic (Ojeda, 1992). Greater plurals may imply an excessive number or else all possible instances of the referent.

Number Mismatches and the Agreement Hierarchy

Nominal number may be realized directly on the noun phrase; it may also be marked on the verb (agreement). In the straightforward cases the values of number match. There are also many instances where we find a mismatch, and English is an especially rich source here. An interesting mismatch involves nouns which are singular morphologically and (typically) have a normal plural and yet, when singular, may take plural agreement, particularly in British English:

(10) *the committee have decided.*

Having an agreement choice here is made possible by the semantics of the noun. However, the likelihood of examples like (10) being acceptable depends on the variety of English involved, and speakers from different parts of the world have opposing judgments. Speakers of different varieties were asked to consider sentences apparently produced by nonnative speakers of English and to correct them where necessary (data from Johansson, 1979: 203; Bauer, 1988: 254). The relevant test sentence was:

(11) *The audience were enjoying every minute of the show.*

(Table 2) For each variety, *n* is the number of respondents, and the other figures are the percentage giving each response. There is substantial divergence between the varieties. Most speakers of British English were happy with the example as given, as were the

Table 2 Judgments on agreement with 'Committee-Type' nouns in three varieties of English

Response (%)	*Variety*		
	GB (n = 92)	*US (n = 93)*	*NZ (n = 102)*
No correction	77.2	5.4	72.5
Was enjoying	15.2	90.3	20.6
Other response	7.6	4.3	6.9

GB = Great Britain; US = United States; NZ = New Zealand.

Table 3 Agreement in written and spoken American English (Levin, 2001: 76)

	Verbs		*Relative pronouns*		*Personal pronouns*	
	n	*% plural*	*n*	*% plural*	*n*	*% plural*

majority of New Zealand English speakers (for further comparative data see Levin, 2001; and Corbett, 2006).

Another source of variation is the 'agreement target'; while Table 2 is concerned with the predicate, it is known that the relative frequency of plural agreement is different for other agreement targets such as the personal pronoun. So let us examine the different agreement targets. In attributive position there is no choice, only singular is possible:

(12) *that committee . . . / *those committee.*

In the predicate, as we know, there are two possibilities; both numbers are possible in British English:

(13) *The committee has/have agreed to reconvene.*

The English relative pronoun does not mark number, but it controls number agreement in its clause and so its number can be inferred:

(14) *the committee, which has decided . . . / the committee, who have decided . . .*

Both numbers are possible. This is also the case with the personal pronoun, and here speakers of American English admit the plural too:

(15) *The committee . . . It . . . / They . . .*

Thus, with such nouns, for speakers of British English, syntactic or semantic agreement is possible for all agreement targets, except attributive modifiers, where only syntactic agreement is acceptable. Levin (2001: 76) counted examples of these agreements with nouns like *committee* in American English, in a corpus from the *New York Times* (NYT) and from the Longman Spoken American Corpus (LSAC) (Table 3).

The picture is remarkably clear. Plural agreement is more common in spoken rather than written language. Moreover, the choice depends on the syntactic position. In attributive position we find only singular agreement. Plural agreement is increasingly possible in the predicate, the relative pronoun and the personal pronoun.

These data fit into a much more general pattern based on the agreement hierarchy, which comprises four target types (Figure 2). Possible agreement patterns are constrained as follows:

> For any controller that permits alternative agreement forms, as we move rightwards along the agreement hierarchy, the likelihood of agreement with greater semantic justification will increase monotonically (that is, with no intervening decrease).

The agreements with committee-type nouns conform to this typological claim, and there is a good deal of further evidence, both from number, and from gender (Corbett, 1991: 225–260, forthcoming).

The English examples are well known, but the phenomenon is found much more widely. For instance, Samoan has several such nouns, some morphologically simple, like *aiga* 'family,' and some derived, like '*au-pua'a* 'group of pigs':

(16) Ua momoe uma le aiga
PERF.V sleep.PL all ART.SING family
'the whole family were asleep'
(O lou igoa o Peko)

(17) 'A tete'i le
but suddenly.awake.PL ART.SING
'au-pua'a . . .
COLL-pig
'When the pigs suddenly awake . . .'
(Moyle)

Note that the article is singular, but the verb is plural; the use of the verb in the plural is frequent but not obligatory (Mosel and Hovdhaugen, 1992: 91, 443, details of sources there). The reason for the potential choice of agreement in these cases is clear. We have seen that the choice may be influenced by language variety but it is also constrained by linguistic factors, notably the agreement hierarchy.

Number and Numerals

In the discussion of number distinctions, we left out any mention of numerals. This is because they can

Attributive < Predicate < Relative pronoun < Personal pronoun

Figure 2 The agreement hierarchy.

have a strangely distorting effect on number use. There are languages like English, where numerals above 'one' typically require the plural *(two cats*, not **two cat*). On the other hand, there are languages where the indication of number by the numeral is sufficient, and the noun stands in the singular, as in Bagvalal and Hungarian, among others. And then there are languages which have both options, as is generally true of Slavonic languages. Taking Russian as our example, *odin* 'one' takes a singular noun; *dva* 'two,' *tri* 'three' and *četyre* 'four,' when themselves in the nominative, take a noun in the genitive singular (a situation which has arisen through the loss of an earlier dual); and *pjat'* 'five' and above, when in the nominative, take a noun in the genitive plural. Complex numerals govern the noun according to the last element of the numeral. The numeral phrases that result from the rules given can in turn produce interesting mismatches when predicate agreement is involved.

Conclusion

Number is indeed a more complex category than is generally recognized, and the English system, although a common one, is at one extreme of the typological space. We noted that, number may be a verbal category as well as a nominal one (but the possibilities are rather more restricted for verbal number). We also saw that number need not be obligatory, that the range of items that distinguish number varies dramatically from language to language, that the semantics of number is affected by the particular item involved, and that the values of the number category can be just two or, in various combinations, up to five. When number is marked by agreement, the values of controller and target do not always match, but the patterns of mismatching are constrained. Complex issues that we have not been able to address here include various interactions, notably between the forms of marking of number, the particular nominals that distinguish number in a given language, and the systems of number values. For these see Corbett (2000).

Human beings, as well as animals, seem to be genetically endowed with some mathematical abilities including a fundamental sense of quantity: most researchers, in fact, now believe that evolution developed a specialized mechanism for number appreciation and processing (Gelman and Gallistel, 1978; Meck and Church, 1983; Fuson, 1988; Wynn, 1990; Dehaene, 1997; Butterworth, 1999; Brannon and Terrace, 2000). This conclusion rests in part on research on human infants: infants are at least able to discriminate between small numbers of entities, can enumerate physical actions, actions sequences, and sounds, and can match a number of sounds to the same number of material objects (Wynn, 1998).

Numbers are properties of objects in the external world that are mentally represented as abstract concepts. The numerosity of a collection of elements is in fact independent of physical attributes. Most researchers (Meck and Church, 1983; Gelman and Gallistel, 1992) agree that numerosity is mapped into a memory representation via a 'accumulator,' a device that sums impulses coming from the elements of a collection. In long term memory the appreciation of numerosity is confronted with previous experience. The internal representation of a number is thought to be analogical and its precision decreases with numerosity. Quantification, i.e., the process of capturing numerosity and accessing to the correspondent mental representation, is performed via three basic tasks: subitizing, counting, and estimation.

'Subitizing' refers to the ability to correctly appreciate small quantities, apparently without serial processing. The idea that subitizing differs from counting, not unanimously accepted, rests mainly on the finding that reaction times to number appreciation are the same for quantities inferior to four elements and increase exponentially thereafter, where counting or estimation become necessary.

Counting consists of pairing each element of a collection to a number word and considering the last assigned word as representing the numerosity of the collection: this latter property is called 'cardinality' The concept of 'ordinality' acquired at the age of

Numbers: Calculation

C Semenza and A Granà, University of Trieste, Trieste, Italy

© 2006 Elsevier Ltd. All rights reserved.

Human beings, as well as animals, seem to be genetically endowed with some mathematical abilities including a fundamental sense of quantity: most researchers, in fact, now believe that evolution developed a specialized mechanism for number appreciation and processing (Gelman and Gallistel, 1978; Meck and Church, 1983; Fuson, 1988; Wynn, 1990; Dehaene, 1997; Butterworth, 1999; Brannon and Terrace, 2000). This conclusion rests in part on research on human infants: infants are at least able to discriminate between small numbers of entities, can enumerate physical actions, actions sequences, and sounds, and can match a number of sounds to the same number of material objects (Wynn, 1998).

Numbers are properties of objects in the external world that are mentally represented as abstract concepts. The numerosity of a collection of elements is in fact independent of physical attributes. Most researchers (Meck and Church, 1983; Gelman and Gallistel, 1992) agree that numerosity is mapped into a memory representation via a 'accumulator,' a device that sums impulses coming from the elements of a collection. In long term memory the appreciation of numerosity is confronted with previous experience. The internal representation of a number is thought to be analogical and its precision decreases with numerosity. Quantification, i.e., the process of capturing numerosity and accessing to the correspondent mental representation, is performed via three basic tasks: subitizing, counting, and estimation.

'Subitizing' refers to the ability to correctly appreciate small quantities, apparently without serial processing. The idea that subitizing differs from counting, not unanimously accepted, rests mainly on the finding that reaction times to number appreciation are the same for quantities inferior to four elements and increase exponentially thereafter, where counting or estimation become necessary.

Counting consists of pairing each element of a collection to a number word and considering the last assigned word as representing the numerosity of the collection: this latter property is called 'cardinality' The concept of 'ordinality' acquired at the age of

about 30 months, refers to the ability to judge which of two different quantities is larger.

According to Gelman and Gallistel (1978, 1992), cardinality is part of innate mathematical knowledge. Such knowledge would also include realizing that: (a) each element must correspond to one verbal label only; (b) a conventional order rules verbal labels; (c) counting applies to any collection of objects; and (d) changing the labeling order does not modify the numerosity of the collection. A separate ability involves separating already counted objects from those that remain to be counted. Not all authors believe that counting rests on innate knowledge: the alternative view (Wynn, 1998) is that children deduce principles of counting from experience.

Estimation is a quick but less accurate process that applies also in the manipulation of internal representations. Several variables, besides objective numerosity, have been shown to influence estimation: the physical properties of the stimuli, their spatial disposition, practice in the tasks, visual clarity, etc. Estimation, however, heavily depends on psycho-physic laws, like Fechner's and Weber's, that also affect internal representations (Krueger, 1984) like the 'number line' a content of imagery that, in the majority of subjects, is thought to support number understanding.

Number processing and calculation have a complex relation with processing of language. As a consequence, neuropsychological disorders affecting the two domains, acalculia and aphasia, are often overlapping and sometimes intimately intertwined. Both linguistic and mathematical functions are largely sustained, in right-handed subjects, by the left hemisphere, whose lesions often feature aphasia as well as acalculia (in a series of 50 left hemisphere patients studied by Delazer *et al.*, 1999, none of the 37 aphasics was error free in calculation). This connection may not be the result of chance evolutionary events. Semenza *et al.* (2004) recently showed that a series of patients suffering from aphasia as a result of right rather than left hemispheric lesions were nonetheless all affected by some form of acalculia. This finding lead to the speculation that linguistic and mathematical faculties, no matter how anatomically and functionally independent from each other, developed from the one hemisphere endowed with the 'recursive faculty,' a combinatory capacity at the basis of both faculties (Hauser *et al.*, 2002).

This said, one should be cautious in drawing firm conclusions about a stronger relationship between representation and processing of language and math. First, statistical associations between deficits do not allow to infer causal relationships between cognitive functions: associations may stem from common underlying resources (such as attention) or just because two functions have neighboring neuroanatomical implementations. Second, empirical evidence argues against an obligatory verbal basis of calculation processes: indeed reliable double dissociations between calculation and language have been reported. Thus global aphasics have been described still demonstrating remarkable arithmetical skills, while severe acalculics have been observed with no detectable language impairment. The observation, in particular, of a nonaphasic patient who entirely lost her knowledge of numbers and number concepts above the numeral four was held as evidence that numbers constitute an independent semantic domain. The same sort of double dissociation may be found when written rather than oral language skills are considered. In the same way, neuropsychological dissociations have been reported of math faculties with general cognitive skills: acalculic patients can still show a higher than average I.Q., while, in contrast, patients with very poor intelligence (including *idiot savants*) may yet be able to solve complex arithmetical problems.

The deduction here is that while it is possible that some subcomponents impinge on a common basic function, the independence between mathematical skills and other cognitive skills, including language, seems proved to a large extent. This fact is reflected in neuropsychological literature where, since the very early studies on acalculia, the intuitive distinction has been commonplace between 'primary' acalculia and acalculia 'secondary' to disorders (pivotally alexia, agraphia, and spatial deficits) interfering with peripheral aspects of number and calculation processing.

Cognitive analyses of neuropsychological deficits, undertaken in the past three decades, allow nowadays extremely fine-grained distinctions among different processing and representational subcomponents of both the number system and calculation. The anatomical correlation of functions has also made some progress from the original, still basically correct, idea, that, with the exception of some spatial components located in the right hemisphere, most math skills are located in the left parietal lobe. One cognitive model, the 'triple code' model (Dehaene and Cohen, 1995), is based on recently discovered anatomical correlations. The model, while assuming that Arabic and magnitude representation of numbers are available to both hemispheres in the vicinity of the parieto-occipito-temporal junction (but extending to the occipito-ventral on the left), assigns the verbal representation underlying the retrieval of arithmetical facts (i.e., single digit problems, like tables, that are, in learned calculators, retrieved from long term memory rather than calculated) exclusively to the left

hemisphere; only the left hemisphere would possess the representation of the sequence of words corresponding to verbal numerals and lexical mechanisms for identifying and producing spoken numerals; these lexical mechanisms, not specific for numbers, would be implemented in the classic language (Broca's and Wernicke's) areas, including the inferior frontal and the superior and middle temporal gyri, as well as basal ganglia and thalamic nuclei. Within the left parietal lobe, three major circuits for number processing were recently identified (Dehaene *et al.*, 2003): a core system, called into action whenever numbers are manipulated and quantity processing is required, would be located in the horizontal segment of the intra-parietal sulcus; a left angular gyrus area, in connection with other left hemisphere areas, would support the retrieval of arithmetic facts, and a bilateral posterior superior parietal system would support attention on spatial dimensions (including the number line).

Number processing is now considered, on the basis of evidence brought about by cases of double dissociation, to be independent from calculation. Processes dealing with numbers are very often 'transcoding' processes, that transform a number from a given representational format into another format. Thus, in the contemporary Western culture (other codes, e.g., the Roman code, have been used or are used in other cultures), a task like reading aloud presupposes transcoding Arabic or alphabetically written numbers into spoken number words; in writing on dictation the reverse transcoding process is at work. Other common transcoding tasks are, for example, number repetition or number transformation from one code into the other (e.g., 'three' into '3' or vice versa). How does the cognitive system perform such tasks? Patients committing revealing patterns of errors in these tasks have been described. The most interesting findings concern two main types of transcoding errors: 'lexical' and 'syntactic' errors (Deloche and Seron, 1982). These errors most often cooccur but are sometimes observed in relative isolation from each other, reflecting independent 'lexical' and 'syntactic' processing mechanisms.

The number lexicon constitutes the collection of the symbols and of simple number words. The 'number syntax,' shown, on the basis of neuropsychological dissociations, to be independent from language syntax, defines the set of acceptable structures formed by combining the basic lexical elements. A semantic component in the system allows attribution of meaning to each sequence.

The verbal numeral system is composed of different lexical primitives (i.e., words) organized in four different classes: the Units or Ones (from one to nine), the Teens (from eleven to nineteen), the Decades (from ten to ninety), and the Multipliers. These last includes words like hundred, thousand, or million, which according to their position in a sequence are in sum (e.g., hundred and four [$100 + 4$]) or are in a product relationship (e.g., four hundred [4×100]) with the lexical primitives. The Arabic numeral system has a limited lexicon that includes the digits from 1 to 9, whose 'position' within numerals determines the power of 10 by which it must be multiplied (e.g., 487 has the value of $4 \times 10^2 + 8 \times 10^1 + 7 \times 10^0$) and the digit 0, that indicates the absence of a given power in the base of the number (e.g., in 407, 0 stands for 0 decades). Zero has a unique role: it never appears in the leftmost position, where it would not make a well-formed integer number.

The lexical processes are thus retrieved on the basis of knowledge of the correct number class and of the position within the class. 'Lexical errors' consist of the incorrect production of one or more of the individual elements in a number (e.g., 5 instead of 6, 45 instead of 55, 1305 instead of 1405).

The combination of lexical primitives leads to the formation of complex numerals. Complex numerals can be conceived as multiplicative-additive structures that can be described as sequences of embeddings of multiplicative and additive relationships. Thus every nonprimitive number is build up by the application of 'syntactic' rules (Power and Dal Martello, 1990): the 'concatenation rule' and the 'overwriting rule.' The concatenation rule is applied when the multiplier (e.g., hundred) is in a product relation with the primitives (e.g., five hundred [5×100]), while the overwriting rule is applied when the multiplier is in a sum relation (e.g., hundred and five [$100 + 5$]) with the primitive numbers. Evidence of these distinct mechanisms comes from both developmental and neuropsychological studies. The overwriting rule is generally more difficult to apply, and in some cases are the almost exclusive type of error, but cases have been described with relatively more errors involving the concatenation rule.

Syntactic errors are thus errors whereby the power of 10 is wrong with respect to the target and are often violations of the concatenation (e.g., '610043' instead of '643') or of the overwriting rules ('60043' instead of '643'); deletions of one or more zeros also occur ('46' instead of '406') or deletions of a multiplier ('1305' instead of '5305'). A recently described patient (Granà *et al.*, 2003) directed the attention of researchers to an important distinction, that between lexical zeros and syntactic zeros, the errors the patient made were exclusively on syntactic zeros. Lexical zeros are semantically derived zeros, like those in tens (e.g., the zero in '20,' and the first zero

in '20104'), that originate from a numerical concept, while syntactic zeros are syntactically produced as the result of syntactic rules, a concatenation rule plus an overwriting rule, leaving one or more intermediary zeros (e.g., the zeros in '12004'). Syntactic zeros are thus more difficult to manipulate.

Number manipulation deficits can selectively concern both production and comprehension and the Arabic or the verbal code. Patients have been reported with selective deficits for particular numbers such as 7 or 9. One still-debated point is whether or not number transcoding and calculation necessarily imply semantic mediation via a central abstract semantic representation and whether asemantic, code-specific routes exist besides the semantic one (different models have been proposed on this subject: McCloskey, 1992; Campbell and Clark, 1992; Cipolotti and Butterworth, 1995; Seron and Noel, 1995; for reviews see Noel, 2001 and Cipolotti and van Harskamp, 2001).

The nature of the semantic representation is also controversial. While, for instance, McCloskey (1992) assumed a precise representation even for large numbers, Dehaene and Cohen (1995) hypothesized an analogue magnitude representation coding for approximate quantity. The existence of this last representation and of a spatial mental number line would be documented by the SNARC (Spatial-Numerical Association of Response Codes) effect (Dehaene *et al.*, 1993), whereby, within a given interval, smaller numbers tend to be preferentially responded to with the left hand, whereas the reverse is true for large numbers. This effect has been shown to hold at least with one-digit numbers, and in speakers of languages that are written from the left to the right, whereas the effect is inverted in speakers of languages with right-to-left writing.

Ordinality and cardinality were also shown to dissociate in patients. A selective impairment with number cardinality has in fact been reported: this patient could correctly order any sequence of numbers, while unable to add 1 to a given number!

With respect to the number system, the calculation system is relatively less studied. However, with a major contribution from neuropsychology, the relatively independent domains of arithmetical signs, arithmetical number facts and rules, calculation procedures, approximate calculation, and conceptual knowledge have been investigated to a large extent.

An independent system for arithmetical signs is suggested by the relatively rare finding of patients unable to understand and name arithmetical signs and performing otherwise correct calculation according to their misidentification.

An independently stored system containing overlearned, quickly retrievable single digit problems (arithmetical facts) is also thought to be acting in calculation (Ashcraft, 1992). This system is subject to the widely investigated problem-size effect, which refers to the observation that difficulty of simple arithmetic combinations generally increases with numerical size. Arithmetical facts, *vis-à-vis* neuropsychological evidence, seem to be segregated according to the type of operation. Thus patients are there, for example, with selective disturbances of table facts only. This segregation appears also at the level of more complex operations (Cipolotti and van Harskamp, 2001). Disturbances of arithmetical facts can occur both in the memory storage and in the retrieval.

Arithmetical rules are distinct from facts and include problems where one of the elements (e.g., the multiplier or the addend) can be substituted by any number (for example, $n+1$, $n-1$, $n\times 1$, $n/1$, $n+0$, $n-0$, $n\times 0$). Rules involving zero are particularly difficult to learn and can be selectively disturbed.

Arithmetical procedures, concerning the algorithms necessary for each type of operation, are also stored independently from each other. As a consequence, acquired disturbances of procedures constitute a rather heterogeneous picture and selective deficits of multiplication or subtraction only have been described. Work on normal learners (Van Lehn, 1986) highlighted systematic, consistent errors known as bugs at certain points of the procedure. Semenza *et al.* (1997) on the basis of selective cases, also distinguished memory problems for the procedural algorithm (typically resulting in systematic misapplication of some specific rule) and monitoring problems, deriving from the inability to devote attention and keep track of each specific step in the procedure. Thus, while memory patients (Girelli and Delazer, 1996) commit, just like normals, errors of the bug type, monitoring patients, while always starting the operation in the correct way, would then make an increasing and inconsistent number of errors of all sorts, have little awareness about the precision of the performance and end the operation with difficulty. It has been recently suggested the possibility that selective right hemisphere lesions might compromise the ability to use a spatially based schema that, in complex operations, would help in keeping the single substeps together by representing the information of where exactly each substep should be placed. This theory is argued to be in line with proposals made by psychologists in the early decades of last century (see Hartje, 1987 for a review).

While the application of procedural knowledge does not require conceptual understanding of each step of the procedure and is applied only in already

familiar tasks, what has been called conceptual knowledge (Hittmair-Delazer *et al.*, 1994), in contrast, implies understanding of arithmetical operations, and the laws and principles pertaining to these operations. Also labeled 'adaptive expertise,' it may or may not be explicitly known as such to the calculator, it allows one to make inferences and can be flexibly adapted to new tasks. Examples of this sort of knowledge are potentially infinite. Delazer's *et al.* (2003) battery for the evaluation of mathematical deficits, for example, includes the following principles, allowing a calculator to answer the question 'given X, what is the result of Y?': the 'commutativity' principle (e.g., X: $22 \times 31 = 682$; Y: $31 \times 22 = ?$), repeated addition ($12 \times 4 = 48$; $12 + 12 + 12 + 12 = ?$), '10a × 10b' ($45 \times 8 = 360$; $450 \times 80 = ?$), 'a−1 × b' ($94 \times 5 = 470$; $93 \times 5 = ?$), multiplication/division invariance ($71 \times 9 = 639$; $639/9 = ?$). Such knowledge is independent from other mathematical notions and abilities. Hittmair-Delazer and coworkers described patients unable to retrieve number facts who brightly used their residual knowledge to overcome their difficulties with tables (e.g., $7 \times 8 = ?$; $7 \times 10 = 70$; $7 \times 2 = 14$; $70 - 14 = 56$), or, while unable to solve facts as simple as $3 + 2 = 5$, had no difficulty with algebraic expressions such as $(ac + bc)/c = a + b$! Conversely, there are patients who flawlessly retrieve arithmetical facts while showing no understanding of mathematical concepts whatsoever.

Numeral Systems: Their Structure and Development

Quantification is essential for our cognition of the world. To quantify is to establish the limits of an entity in a relative way. Each entity is defined by its limits and identified by the relativity of its limits. It is discrete. For example, a piece of sugar is a discrete entity, which can have further spatial properties not attributable to its source, the amorphous mass of sugar.

Discreteness emerges from quantification. Discrete entities can be grouped together so as to form sets. Sets can be homogeneous or heterogeneous; they can contain many entities or be empty, yet they always have clear limits. By having clear limits, a set is an entity, too, an entity of a higher order.

Set formation presupposes entities, themselves a cognitive product of either quantification or (if the entities have already been quantified) identification. The primary act of set formation involves abstraction from all but a classifying property. An example is found in tally sticks with notches on bones, which originated in Africa around 37 000 years B.C. and in Europe some millennia later. The notches represent quantified entities; the tally stick contains a set (**Figure 1**).

Counting is based on classification, accumulation, and grouping. Cognitive units of counting are numbers; their symbolic expressions in language are numerals.

Figure 1 African tally stick (37 000 B.C.), probably representing the moon cycle (29 notches).

Grouping of entities is an essential feature of number systems, with the effect of establishing bases (in addition to digits such as '1'). Across cultures, primitive counting on fingers and toes led to the establishment of the group of '5' – symbolized by a hand – as a basis for further counting. Significantly, counting on fingers and toes operates with the base of '5' (i.e., five fingers or a hand), the base of '10' (i.e., two hands), and the base of '20' (i.e., fingers and toes or hands and feet). Contemporary examples in active use are found in Papua New Guinea, where, e.g., the Aghu language symbolizes '5' by the word for 'hand', whereas Kombai, Korowai, and Wambon symbolize '5' by the word for 'thumb'. Similar systems are found, e.g., in Mullukmulluk in Australia (cf. Greenberg, 1978: 257) and in Bantawa in east Nepal (where the numeral for '5' is *ụkchuk* 'one hand', '10' is *hụachuk* 'two hands', and '20' is *reṭkachuk* 'four hands'; cf. Gvozdanović, 1985: 137). Many systems known as advanced started from a quinary base, for example, Sumerian from the 4th millennium B.C. in Mesopotamia (**Table 1**).

Comparative studies of Indo-European have shown that Proto-Indo-European (PIE) words for '5' and '10' are also based on counting by hand. Thus, PIE *$*penk^w(e)$* '5' is connected, e.g., with Old High German (OHG) *fūst* and Russian *pjast'* 'fist',

originally referring to the hand clenched to form a fist as a symbol of 'five' (cf. Winter, 1992: 17), whereas PIE **dekm̥t* '10' has been reconstructed as **de-km̥t* 'two hands', and **km̥tom* < *dkm̥tom* '100' as either the genitive plural of the neuter collective noun **dkm̥t-* (i.e., ** dkm̥t dkm̥tom* 'a decade of decades', cf. Szemerényi, 1960: 139–140), or a derivative with *–to-*, signifying the limiting point in the series of decades (cf. Coleman, 1992: 404). Indeed, the base of '100' was the highest decimal base in Proto-Indo-European (as the reconstruction of '1000' **ghes-lo-* on the basis of Aryan and Greek fails to account for the other Indo-European languages; cf. also Szemerényi, 1960: 1).

Historically seen, the development of advanced numeral systems was connected with astronomy, geometry, and calendar construction, in addition to stock administration and trade. This applies to the ancient Egyptian decimal system (since the 5th millennium B.C.) as well as to the Sumerian and later Akkadian and Babylonian sexagesimal system (cf., e.g., Neugebauer, 1947: 37 concerning the calculation of lunar phases).

Apart from bases of unrestricted productivity, rudimentary bases have been recorded, for example, in duodecimal counting of Benue-Congo languages (involving a base of '12'), later replaced by a decimal system, or in Sora, a Munda language (cf. Greenberg, 1978: 270) (related to it were probably also the 'big hundreds' transitionally present in Northern Germanic [equalling '120']). Smaller rudimentary bases have been attested in rural communities, such as base '4' in Barbareño (a Chumash language of California; cf. Comrie, 1999: 89), in Tunisian, or in Celtic (cf. Justus, 1999: 61 f.). Yuman languages of Southern California, Arizona, and Baja California, next to Coahulteco a Hokan language, provide examples of limited use of the base '3'. A rudimentary base '2' is found in the central Wintun branch of Californian Penutian (cf. Greenberg, 1978: 279). Rudimentary bases coexist with productive bases, usually of later origin.

The lowest productive base by which all higher productive bases can be divided is called fundamental (cf. Greenberg, 1978: 270). Apart from the rare exceptional types mentioned above, languages are classified by their fundamental bases as quinary (with the fundamental base '5'), decimal (with the fundamental base '10'), vigesimal (with the fundamental base '20'), or sexagesimal (with the fundamental base '60').

The capacity to undergo recursive mathematical operations makes bases into the backbone of numeral systems. The relevant operations and their asymmetrical implications (in the sense of Greenberg's hierarchies (1978: 257–272) are the following:

- addition (e.g., French *dix-neuf* 'ten-nine', i.e., '19'),
- subtraction (e.g., Latin *un-de-viginti* 'one-off-twenty', i.e., '19'); it implies the existence of addition (every minuend is a base of the system or a multiple of a base; a subtrahend is never larger than the remainder);
- multiplication (e.g., English *fifty* [5×10]); it implies the existence of addition (a rare exception is found in a subgroup of the Yuman languages, affiliated to the Hokan stock, which has the first decade only, analyzed as '1', '2', '3', '4', '5', '3×2', '7', '4×2', '3×3', '10');
- division (e.g., Welsh *hanner cunt* 'half hundred', i.e., '50'); it implies the existence of multiplication (division is expressed as multiplication by a fraction, and the denominator of the fraction is always '2' or a power of '2');
- (rarely) overcounting (e.g., older Danish *halv-tred-sinds-tyve* 'half-third-time-twenty', i.e., '50') and 'going-on' operation (e.g., in Mayan and in Finno-Ugric, cf. *Ostyak* '18' as ('8 going-on 20'));
- exponentiation (e.g., Sumerian *geš* '60', *šàr* '3600', *šàr-gal* '*šàr*-big' '216,000').

Bases show up as significant boundaries in language decay, at least at intermediate stages. This may be illustrated by the Tibeto-Burman languages of Nepal (cf. Gvozdanović, 1985: 136), which have been overlayered by the (Indo-European) standard language Nepali, but have preserved their original numerals either up to the fundamental base '5' (symbolized by 'one hand' or by the Proto-Tibeto-Burman form *ngaji*) or up to '3'. The observed regularity demonstrates the cognitive relevance of numeral bases.

Morphology and Syntax of Numeral Expressions

Numeral morphosyntax shows a combination of mathematical and linguistic properties, relating to semantic, morphosyntactic, and pragmatic levels. For numeral morphosyntax Hurford (1987) formulated a so-called 'packing-strategy' principle that states that complex numeral expressions are formed by combining the highest-valued simpler numerals available (e.g., the French numeral for '70' is *soixante dix* [$60 + 10$], not **cinquante-vingt* [$50 + 20$] or **quarante trente* [$40 + 30$]). The point at which a language changes methods for signaling addition is as a rule indicative of a base break. It is typical of Indo-European that such a break occurs between the -teens (cf. English *thirteen–nineteen*, expressed as digit + base) and the upper decades (starting from '20', regionally limited also above '60'). Outside of

Indo-European, pattern discontinuity may be illustrated by Hebrew, where the numeral plurals of '3' to '9' denote the corresponding decades '30' to '90', but the plural of '10' denotes '20'. The next-higher base is '100', for which Hebrew has a separate noun, *meʾa*.

Numeral bases are treated differently from digits. In systems with more than one base, there is a base above which certain regularities hold, e.g., complex expressions consist of a product and a remainder, and the remainder never has a value larger than the next lower base of the total expression (cf. French *soixante douze* '72, i.e., 60 + 12' is possible because the next lower base is '20').

Numeral syntax is usually highly complex, and only a part of this complexity is directly connected with numeral morphology. Typologically interesting is the tendency of the numeral to precede the noun if the descriptive adjective is also in the preceding position, as opposed to variation in the position of the numeral when the adjective follows the noun. An example of the latter is found in Malay, in which the descriptive adjective regularly follows the noun, but the numeral and the classifier may be placed either before or after the noun (the latter option seems to be pragmatically marked).

Numeral morphosyntax exhibits a set of further regularities:

- the numeral 'one' is syntactically an attribute of its denominator;
- numerals expressing bases either are syntactic heads or share headedness with their denominator (cf. Hebrew, in which these numerals have inherent gender); in the development of Indo-European, the lower bases have arguably developed from adjectives to nouns;
- the numerals 'two', 'three', and 'four' have an intermediate status; they may differentiate gender; languages with grammatical dual have a special treatment of 'two';
- many languages have discontinuity of expression around the numerals 'three' and 'four', relating especially to distinct marking for gender, case, indefiniteness, or word order; these phenomena are presumably related to short-term memory limitations (cf. Cowan, 2001);
- in rule-governed variation between the singular and the plural with numerals, the singular is favored with higher numbers, in measure constructions, in indefinite constructions, and with nouns that are inanimate or impersonal (Greenberg, 1978: 283);
- the order noun-numeral is favored in indefinite and approximative constructions (Greenberg, 1978: 284);
- predicate agreement with quantified subjects above the cut-off point around 'three' or 'four' mentioned above is sensitive to animacy and topicality: the singular agreement is preferred with inanimate and non-topical subjects, the plural agreement with animate and topical subjects.

Although quantification takes effect in the logical structure of language, its morphology and syntax depend in part on pragmatics. This shows that quantification permeates all the central levels of language.

Numerical Notation

J Lawler, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Notation is a conventional written system for encoding a formal axiomatic system. Notation governs

- the rules for assignment of written symbols to elements of the axiomatic system;
- the writing and interpretation rules for well-formed formulae in the axiomatic system;
- the derived writing and interpretation rules for representing transformations of formulae, in accordance with the rules of deduction in the axiomatic system.

All formal systems impose notational conventions on the forms. Just as in natural language, to some extent such conventions are matters of style and politics, even defining group affiliation. Thus, notational conventions display sociolinguistic variation; alternate conventions are often in competing use, though there is usually substantial agreement on a 'classical' core notation taught to neophytes.

Excluding logic (*see* **Logical and Linguistic Notation**), mathematics as a whole is divided into three parts, of which one is algebra (roughly, the realm of the discrete, including number theory and combinatorics), another geometry (roughly, the realm of the visibly codable, including topology), and the third what ordinary people call calculus, but which is spoken of by mathematicians as analysis (roughly, the realm of the continuous, including statistics, differential and integral calculus, theory of functions, and complex variables). All these areas overlap and grow into one another fractally; in particular, they crucially involve the concept of number.

Numbers and Arithmetic Symbols

Though there appear to be some cultures where counting and numbers are unknown (see Everett, 2005), almost all languages contain some numbers, and almost all cultures practice counting and other mathematical activities. The written representation of quantities and numbers is as old as, and may even predate and prefigure (see Schmandt-Besserat, 1992; Zimansky, 1993), writing itself. After alphabetic writing was developed, it was normal to use individual letters to represent particular numbers in an additive system such as Roman numerals, where, for instance, *MDCCVII* represents $1000 + 500 + 100 + 100 + 5 + 1 + 1$, or 1707. Similar systems existed for ancient Greek and Hebrew; even after the widespread use of Hindu/Arabic numerals, the Hebrew system of alphabetic number representation survived as a Kabbalistic numerological system known as Gematriya, in which the number associated with any Hebrew word has gnostic significance. See Ifrah (1991: ch. 2) in Barrow (1992), and Pettersson (1996) for history. The Hindu/Arabic numerals, with their positional notation, were originally developed in India during the Gupta empire and spread to the Muslim world, whence they made their way to Europe after the Crusades. In positional notation, the position of each numeral in a series indicates the power of the base that it enumerates; thus, *1707* in base ten represents $(1 \times 10^3) + (7 \times 10^2) + (0 \times 10^1) + (7 \times 10^0)$. Such a notation (including zero, which is necessary for it to work) represents an enormous advance in numeration over additive systems, because it makes possible algorithmic calculations such as long division.

Hindu/Arabic numerals in base ten are all but universal in the writing systems of the modern world. While the decimal (base ten) system is the norm, in principle any numeric base can be used, and several have been: the Babylonian numeric system was sexagesimal (base 60, from which we inherit the 360° circle and the 60-minute hour); the Mayan system was vigesimal (base 20); vestiges of a duodecimal (base 12) system remain in English vocabulary (*dozen*, *gross*); and several systems based on powers of 2 – binary (base 2, digits *0* and *1*), octal (base 2^3,

Notation is a conventional written system for encoding a formal axiomatic system. Notation governs

- the rules for assignment of written symbols to elements of the axiomatic system;
- the writing and interpretation rules for well-formed formulae in the axiomatic system;
- the derived writing and interpretation rules for representing transformations of formulae, in accordance with the rules of deduction in the axiomatic system.

All formal systems impose notational conventions on the forms. Just as in natural language, to some extent such conventions are matters of style and politics, even defining group affiliation. Thus, notational conventions display sociolinguistic variation; alternate conventions are often in competing use, though there is usually substantial agreement on a 'classical' core notation taught to neophytes.

Excluding logic (*see* **Logical and Linguistic Notation**), mathematics as a whole is divided into three parts, of which one is algebra (roughly, the realm of the discrete, including number theory and combinatorics), another geometry (roughly, the realm of the visibly codable, including topology), and the third what ordinary people call calculus, but which is spoken of by mathematicians as analysis (roughly, the realm of the continuous, including statistics, differential and integral calculus, theory of functions, and complex variables). All these areas overlap and grow into one another fractally; in particular, they crucially involve the concept of number.

Numbers and Arithmetic Symbols

Though there appear to be some cultures where counting and numbers are unknown (see Everett, 2005), almost all languages contain some numbers, and almost all cultures practice counting and other mathematical activities. The written representation of quantities and numbers is as old as, and may even predate and prefigure (see Schmandt-Besserat, 1992; Zimansky, 1993), writing itself. After alphabetic writing was developed, it was normal to use individual letters to represent particular numbers in an additive system such as Roman numerals, where, for instance, *MDCCVII* represents $1000 + 500 + 100 + 100 + 5 + 1 + 1$, or 1707. Similar systems existed for ancient Greek and Hebrew; even after the widespread use of Hindu/Arabic numerals, the Hebrew system of alphabetic number representation survived as a Kabbalistic numerological system known as Gematriya, in which the number associated with any Hebrew word has gnostic significance. See Ifrah (1991: ch. 2) in Barrow (1992), and Pettersson (1996) for history. The Hindu/Arabic numerals, with their positional notation, were originally developed in India during the Gupta empire and spread to the Muslim world, whence they made their way to Europe after the Crusades. In positional notation, the position of each numeral in a series indicates the power of the base that it enumerates; thus, *1707* in base ten represents $(1 \times 10^3) + (7 \times 10^2) + (0 \times 10^1) + (7 \times 10^0)$. Such a notation (including zero, which is necessary for it to work) represents an enormous advance in numeration over additive systems, because it makes possible algorithmic calculations such as long division.

Hindu/Arabic numerals in base ten are all but universal in the writing systems of the modern world. While the decimal (base ten) system is the norm, in principle any numeric base can be used, and several have been: the Babylonian numeric system was sexagesimal (base 60, from which we inherit the 360° circle and the 60-minute hour); the Mayan system was vigesimal (base 20); vestiges of a duodecimal (base 12) system remain in English vocabulary (*dozen*, *gross*); and several systems based on powers of 2 – binary (base 2, digits *0* and *1*), octal (base 2^3,

digits 0–7), and hexadecimal (base 2^4, digits 0–9 plus *A–F*) – are in common use in computing contexts.

By contrast with the numerals, all of the usual symbols for arithmetic operations (+, −, ×, ÷) are of European origin, originating among a congeries of symbols used between the 15th and 17th centuries. + is simply the stylized letter T of *et*, an early ampersand. The symbol for division (÷), now seen as an obvious mnemonic of the fraction notation with a horizontal bar introduced by the Arabs, was in fact originally used in Europe for subtraction, and it is from this sign that the modern − sign comes. Finally, × is only one of several symbols for multiplication, introduced and promoted by William Oughtred (1574–1660) in the *Clavis Mathematicae* (1631). Other multiplication notation in use today includes the raised dot ($a \cdot b$), which Leibniz preferred, and simple juxtaposition (ab), which appears to have been the original notation in India, dating from the 10th century and appearing sporadically in Arabic and European sources afterward. By the 18th century, these symbols had become general in European mathematical notation.

Other Symbols

Mathematics is a gigantic intellectual area, famously unapproachable by the uninitiated, replete with multiple notational conventions and the materials and will to invent new ones. Considering the size of the field and the elaborate profusion of its notation, this article can do no more within its space constraints than touch on the notations of several areas (besides logic) that impinge on natural language, and remark on general notational tendencies in mathematics.

One example is the notation used in modern integral and differential calculus, which descends from Leibniz's original invention in the 17th century; Newton famously invented calculus independently before Leibniz, but published later. More importantly for our purpose, he used a different notation which, while patriotically employed in English mathematics for the next century, proved awkward and was eventually abandoned for Leibnizian differentials.

The basic concepts in calculus are the derivative of a function $y = f(x)$ and its integral. The derivative is another function f' whose value at any point x is the instantaneous rate of change with respect to x of the value y of $f(x)$. This function in turn has its own derivative f'', which is thus the second derivative of f, and so on. Newton used overdot $\dot{y}$ for the derivative. The integral of a function is another function whose value represents the area between the curve and an axis. Newton used overbar $\bar{y}$ to represent the integral.

While first and second derivatives are still quite commonly indicated with prime marks, replication of dots and primes becomes difficult when speaking of higher derivatives, or when using a variable. Leibniz's notation, unlike Newton's, used a ratio between the differentials dy and dx (infinitesimal increments in y and x) to represent the derivative. Second and higher derivatives are indicated by exponents on the differentials; thus $f'(x) = dy/dx$, and $f''(x) = d^2y/dx^2$, producing a natural operator notation d/dx for differentiation, in contrast to Newton's notation, which did not lend itself to such generalization.

For integrals Leibniz used a special operator, the long-S integral symbol $\int f(x)\, dx$. The differential dx after the function in this notation is a mnemonic for multiplication, just as the ratio between differentials symbolizes division in the derivative notation. Leibniz's convention recalls the fundamental theorem of calculus (i.e., derivative and integral are inverses) by use of the inverse operations multiplication and division to represent them; by contrast, Newton's notation was arbitrary and had no mnemonic value.

Following the invention of the calculus, mathematics endured for several centuries a disconnect between axiomatic theory and actual practice. Calculus worked, for reasons which mathematicians could not explain, and about which engineers did not care. The result was that practice got very far ahead of axiomatic theory, until at the beginning of the 19th century, mathematicians resolved to put such axiomatization at the front of their goals.

By 'axiomatization,' mathematicians mean the establishment of a system of undefined elements, axioms, and rules of inference for deriving theorems from the axioms, based on the model of Euclidean geometry, which for millennia has stood as the exemplar of pure mathematical thought. This is what is meant in mathematics as a 'formal system'; in linguistics this term has a different sense, since linguists do not establish axioms or prove theorems.

The most significant area of mathematics in this axiomatization effort has been set theory, which now, as a result of the 19th-century work, is taken to underlie all areas of mathematics and logic. Set theory has only three undefined terms: set, element of a set, and inclusion in a set. These are universally symbolized with capital letters to name sets, lowercase letters to name elements in them, and the relation symbol $\in$ for set inclusion, thus $a \in A$ indicates that a is an element of the set A. Sets may also be specified by using curly braces, e.g., the set of English vowel letters is {a, e, i, o, u}, and the set N of natural numbers is {1, 2, 3, . . .}. Since most interesting sets are infinite, or at least very large, simple enumeration is rarely

sufficient; thus one finds qualified set descriptions, e.g., the set of perfect squares can be described as $\{x^2: x \in N\}$, pronounced 'the set of all x squared, such that x is in N.'

From this set convention come all the various uses of parentheses and brackets for inclusion and specification, such as the ordered pair $(0, 1)$ in algebra, which is simply a special set consisting of two elements in order. Exactly the same notation $(0, 1)$ in topology is used to denote an open set, i.e., the set of all points on a line lying between 0 and 1, but **not** including the end-points; if an end-point is included, the notation changes to a square bracket, so that the closed set $[0, 1]$ has a largest and a smallest member, while the open set $(0, 1)$ has neither. In analysis, $(0, 1)$ following a function symbol such as f implies that f is a function of two arguments to be applied to 0 and 1.

Fonts play a more important role in mathematical notation than one might expect, given the arbitrariness of font choice. The problem in mathematics is that there is an infinite number of concepts that one might wish to represent with a simple symbol, but there is a limited number of simple symbols that can be printed easily. Hence, it is common to mix and match Latin, Greek, and Fraktur alphabets (among others), in boldface, italic, and plain variants, each indicating some systematic feature of the concept under discussion. Such use is quite idiosyncratic, with considerable individual variation and specific traditions in each subarea. For instance, in relativity theory, tensor indices use Greek letters when they vary from 0 to 3 and Latin letters when they vary from 1 to 3.

General Tendencies

Mathematical notation, like all mathematics, is an exemplification of the grounding metaphors that structure the field (see Lakoff and Nuñez, 2000). These, in turn, are mostly based on the basic human cognitive activity of predication, instantiated by concepts such as function, operator, or relation, which name various symbols and types of sentencelike symbolic syntax in all areas of mathematics and logic: a function $f(x)$ is a clause with a predicate and argument(s); an equation $a = b$ is a topic–comment clause. All mathematical notation is ultimately pronounceable, a subset of written language, though like Chinese characters it is not language-specific.

Nuuchahnulth

J Stonham, University of Newcastle, Newcastle upon Tyne, UK

© 2006 Elsevier Ltd. All rights reserved.

Nuuchahnulth, also known as Nootka, Nutka, Aht, Takhaht, and *t'aat'aaqsapa*, and by the various dialect designations, is one of the earliest documented languages of Western Canada, with first contact going back to the 1770s. Early work focused mostly on the vocabulary, with word lists being documented by a number of early explorers. The earliest detailed grammatical investigations include those of Knipe (1868), Boas (1890), and Sapir (1924). The name Nuuchahnulth is an anglicized version of *nuučaaḥuł* 'along the mountains' (*nučiˇ* 'mountain(s),'-*aˇḥuł* 'along': ˇ indicates variable length of the vowel). Geographically, the Nuuchahnulth people occupy the west coast of Vancouver Island, from Brookes Peninsula in the north to Bamfield in the south.

Table 1 Nuuchahnulth consonant inventory

Labial	*Alveolar*	*Lateral*	*Alveopalatal*	*Velar/labiovelar*	*Uvular/labiouvular*	*Pharyngeal*	*Glottal*
p	t			k	q		ʔ
ṗ	ṫ			ḱ	q̇	ʕ	
				kʷ	qʷ		
				ḱʷ	q̇ʷ		
	s	ɬ	š	x	x̣	ḥ	h
		ɬʷ		xʷ	x̣ʷ	ḥʷ	
	c	x̌	č				
	ċ	x̌ʼ	č̣				
m	n		y	w			
ṁ	ṅ		ẏ	ẇ			

Nuuchahnulth has a relatively large consonant inventory as shown in Table 1. Conversely, the vowel system is quite simple, involving just the three vowels, /i, u, a/, and a length distinction. There are, in addition, two mid vowels that are only encountered in the long variety, /eˑ / and /oˑ /, at least phonologically, and even then only under certain special circumstances, such as in foreign borrowings. Primary stress is predictable and appears on one of the first two syllables of a word, depending on weight.

Important morphophonological processes include glottalization and lenition, which affect the preceding consonant and depend on the individual suffix triggering the effect (abbreviations: LOC, locative; DUP, duplication; SUF, suffix, MOM momentaneous aspect, NOW contemporaneous, MC momentaneous causatiṽe, SUB subordinate, L lengthening, R reduplication. All data are from Sapir's unpublished fieldnotes, (Sapir, no date), unless otherwise indicated.

(1a) hiitaḥt'iχšiʔaχ
hita-ḥt -'iχ -šiχ -'aχ
LOC-exit woods-go for[L]-MOM-NOW
'They started out of the woods.'

(1b) wišḱum
wišk -'um
angry -on the rocks
'angry on the rocks'

(1c) ʔaayimkiχqas
ʔaya -miik -iχ -qa˘s
many -getter of -MC -1S.SUB
'may I be a getter of many . . .'

(1d) titinkum
DUP-ti -ṅukʷ -im
SUF-wipe -at the hand [R] -thing
'handwiper'

As can be seen from (1a) and (1b), a glottalizing suffix will trigger glottalization of the preceding consonant, whereas a nonglottalizing suffix ((1c) and (1d)) will not. Other common morphophonological processes include labialization, delabialization, vowel coalescence, and ʔ-epenthesis. One further morphophonological process involves a class of vowels labeled variable length; such vowels appear long in the first foot of the word, but are short after that. These are characteristically Wakashan in nature and constitute a special class of vowels.

Morphologically, Nuuchahnulth is extremely complex, with upward of 500 bound derivational morphemes, along with numerous inflectional paradigms. The creative genius of the language is demonstrated by the following words:

(2) ciciḥʔaqχmapt 'crab-apple tree' (< ciḥ 'sour' -ʔaqχ 'inside' -mapt 'plant')
čičiyupḱuk 'spaghetti' (< *čiyup* 'intestines' -*ḱuk* 'resemble')
ṅiikmaɬiičač̌k 'guitar' (< *ṅik* 'scratch' -*maɬ* 'about' -*iiču* 'tool') 'at strings' -*č̌akʷ*

Morphological processes include reduplication, infixation, and suffixation, although lexical compounding is absent. There is a class of lexical suffixes that requires reduplication of some part of the root as a concomitant of the attachment (3a), in addition to reduplication indicating plurality (3b), distributivity (3c), repetition (3d), and other aspectual categories. In fact, double reduplication may occur in contexts in which both derivational and inflectional triggers to reduplication cooccur (DISTRIB, distributivity; REP, repetition; PASS, passive)

(3a) kuukuḥinqiɬ

DUP-ṅup -qimɬ -ayi˘ -'at
DISTRIB-one -classifier -give -PASS
'He gave a dollar to each.'

(3d) tuuxtuuxʷa
DUP-tux -(y)a˘
REP-jump -DUR
'jumping'

Predicates are typically marked for aspect and often for location (e.g., *-'iɬ* 'in the house,' *-'as* 'on the ground, in the village,' and *-'is* 'on the beach'), and bear one of a set of paradigmatic mood/person/number suffixes and other possible markers. Tense is optionally marked on predicates, as is plural for nouns. Nouns may be marked for number, diminutive, augmentative, former/future state, and possession.

Syntactically, Nuuchahnulth may be described as head-initial and head-marking. The most common word order is verb initial, either verb–subject–object or verb–object–subject, although arguments may be omitted. In keeping with its head-marking nature, possessors follow possessees (4a) and relative clauses follow their heads (4b):

(4a) ḥaẇiɬukʔi q$^{\omega}$ayaċiiktaqimɬ
ḥaẇiɬ-uk =ʔiˇ q$^{\omega}$ayaċiik -taqimɬ
chief-POSS =DEF wolf -tribe
'the chief of the wolves'

(4b) łuucsmeʔi yaq$^{\omega}$acʔitq t̓aṅa
łuucsma-ʔiˇ yaq$^{\omega}$-ac -ʔiˇtq t̓aṅa
woman-DEF REL-belong to -3S.REL child
'the woman whose child he was'

In the case of relative clauses, there are two types – headed (4b), involving either *yaq*$^{\omega}$ 'who(m)' or *q*$^{\omega}$*i* 'which,' or headless (5), in which the specifier *ʔiˇ* is attached to the predicate of a relative clause:

(5) qaḥšiχʔi
qaḥ -šiχ =ʔiˇ
die -MOM =DEF
'the dead (ones)'

A process reminiscent of noun incorporation exists, but with a rather broad range of implementation:

(6a) ʔuutẏaaṗaχ [[suuḥaa]$_{N}$]$_{NP}$
ʔu-itẏaap -'aχ suuḥaa
REF-bring . . . as -NOW spring
gift silver salmon
'He brought a gift of silver spring salmon.'

(6b) suuḥ$_i$iitẏaṗat [[t$_i$]$_N$]$_{NP}$
suuḥaa -itẏaap -'at
silver spring salmon -bring . . . as gift -PASS
'He brought a gift of silver spring salmon.'

Elements incorporated may include numerals (7a), adverbs (7b), adjectives (7c), or nouns (6b), always from the object argument. Subjects of unaccusative verbs may also be involved (7d):

(7a) ḥaayumiikuk ʔuḥʔiš muu ʔiiḥtuup
ḥayu -m̓ iˇk$^{\omega}$ -uk ʔuḥʔiš muu ʔiiḥtuup
ten -capture -POSS and four whale
'He captured fourteen whales.'

(7b) ʔiiḥiiɬ χuɬ čapic
ʔiiḥ$^{\omega}$ -iiɬ χuɬ čapac
very -make good canoe
'He made a really nice canoe.'
(Rose, 1981)

(7c) ʔiiḥnaak čapic
ʔiiḥ$^{\omega}$ -naˇk$^{\omega}$ čapac
big -have canoe
'He has a big canoe.'
(Rose, 1981)

(7d) ʔayasuuχ naṁ intʔatḥ
ʔaya -sawiχ naṁ int -'atḥ
many -die Namint -tribe
'Many Namint people died.'

Coordination may involve noun phrases, verb phrases, or intermediate units and may employ one of several conjunctions, including *ʔiš* and *ʔuḥʔiš*, both meaning 'and.' Subordination is marked by special inflectional paradigms and may or may not involve subordinating conjunctions such as *ʔani* 'that,' *ʔuyi* 'when,' etc. There is a marker, *-ʔat*, which has been labeled variously passive, switch reference, or discourse marker. (The debate over the role of this morpheme continues, for which see Kim (2004) and references therein.) For further information on Nuu-chahnulth, the reader is referred to the bibliography appended to this article, in particular the discussions in Davidson (2002), Jacobsen (1979a,b), Kim (2003), Nakayama (2001), Rose (1981), and Stonham (1999, 2004).

History and Politics

ChiNyanja (Nyanja) is a language of the Bantu group of the Niger-Kordofanian language family, and is spoken in parts of eastern, central, and southern Africa. It is spoken in Malawi, where, from 1968 until recently, under the name of Chichewa, it served as the national language. It is also spoken in Mozambique, especially in the provinces of Tete and Niassa, as well as in Zambia and Zimbabwe. In the latter, according to some estimates, it ranks as the third most widely used local language, after Shona and Ndebele. The countries of Malawi, Zambia, and Mozambique overwhelmingly constitute the central location of chiNyanja.

The language derives its name from the lake that is shared by Malawi, Mozambique, and Tanzania, with most if it as part of Malawi. The local word for a large expanse of water is *nyanja*. The people who lived along the shores of the lake and the banks of the Shire River called themselves aNyanja (lake dwellers). The Shire River flows from the southern extremity of the lake, formerly called Lake Nyasa, but now known as Lake Malawi, through southern Malawi into southern Mozambique to join the Zambezi River. The aNyanja (the singular form of which is *mNyanja*, where the prefix *m* is a syllabic nasal) spoke the language called chiNyanja (henceforth, Chinyanja).

Like most languages, Chinyanja has a number of regional dialectal variations. One of these, spoken in the hinterland of Malawi, is called chiChewa (henceforth Chichewa). This dialectal variation is the one that was spoken by the first president of Malawi, the late Dr Hastings Kamuzu Banda (cf. Watkins, 1937). The ascendancy of a Chewa to the presidency in independent Malawi had repercussions on language issues. President Banda argued that the classification of Chichewa as a dialect of Chinyanja was erroneous, deriving from unfortunate aspects of the history of missionary activity in the country, whose early activities were concentrated along the lake. Banda invoked aspects of history, plausible in some ways, to argue that Chichewa was the language of which Chinyanja was the dialectal variation (for pertinent observations, see Marwick, 1963).

The version of the history of the Chewa that Banda espoused was that the people who speak Chichewa, known as aChewa, trace their origins to a group of people known as the Maravi (according to some Portuguese records) who migrated from the lower basin of the Congo in central Africa and eventually settled in the land mass now covered by Malawi, Zambia, and Zimbabwe. Pushed by wars, disease, and other maladies from the Congo area, the Maravi were the first group of Bantu peoples to move and settle in-present day Malawi in the 16th century. Other Bantu groups such as the Tumbuka, Tonga, Yao, Lomwe, and Ngoni moved into Malawi long after the Maravi group had successfully established itself (see Kalipeni, 1996).

The Chewa were led by a powerful leader called Kalonga. He founded in Malawi what later came to be called the Maravi empire. In Malawi he established his headquarters or seat in a place called Mankhamba. Once settled, he decided to extend his influence by

History and Politics

ChiNyanja (Nyanja) is a language of the Bantu group of the Niger-Kordofanian language family, and is spoken in parts of eastern, central, and southern Africa. It is spoken in Malawi, where, from 1968 until recently, under the name of Chichewa, it served as the national language. It is also spoken in Mozambique, especially in the provinces of Tete and Niassa, as well as in Zambia and Zimbabwe. In the latter, according to some estimates, it ranks as the third most widely used local language, after Shona and Ndebele. The countries of Malawi, Zambia, and Mozambique overwhelmingly constitute the central location of chiNyanja.

The language derives its name from the lake that is shared by Malawi, Mozambique, and Tanzania, with most if it as part of Malawi. The local word for a large expanse of water is *nyanja*. The people who lived along the shores of the lake and the banks of the Shire River called themselves aNyanja (lake dwellers). The Shire River flows from the southern extremity of the lake, formerly called Lake Nyasa, but now known as Lake Malawi, through southern Malawi into southern Mozambique to join the Zambezi River. The aNyanja (the singular form of which is *mNyanja*, where the prefix *m* is a syllabic nasal) spoke the language called chiNyanja (henceforth, Chinyanja).

Like most languages, Chinyanja has a number of regional dialectal variations. One of these, spoken in the hinterland of Malawi, is called chiChewa (henceforth Chichewa). This dialectal variation is the one that was spoken by the first president of Malawi, the late Dr Hastings Kamuzu Banda (cf. Watkins, 1937). The ascendancy of a Chewa to the presidency in independent Malawi had repercussions on language issues. President Banda argued that the classification of Chichewa as a dialect of Chinyanja was erroneous, deriving from unfortunate aspects of the history of missionary activity in the country, whose early activities were concentrated along the lake. Banda invoked aspects of history, plausible in some ways, to argue that Chichewa was the language of which Chinyanja was the dialectal variation (for pertinent observations, see Marwick, 1963).

The version of the history of the Chewa that Banda espoused was that the people who speak Chichewa, known as aChewa, trace their origins to a group of people known as the Maravi (according to some Portuguese records) who migrated from the lower basin of the Congo in central Africa and eventually settled in the land mass now covered by Malawi, Zambia, and Zimbabwe. Pushed by wars, disease, and other maladies from the Congo area, the Maravi were the first group of Bantu peoples to move and settle in-present day Malawi in the 16th century. Other Bantu groups such as the Tumbuka, Tonga, Yao, Lomwe, and Ngoni moved into Malawi long after the Maravi group had successfully established itself (see Kalipeni, 1996).

The Chewa were led by a powerful leader called Kalonga. He founded in Malawi what later came to be called the Maravi empire. In Malawi he established his headquarters or seat in a place called Mankhamba. Once settled, he decided to extend his influence by

acquiring more land and having it settled by his subjects. To achieve those objectives he dispatched a number of his matrilineal relatives to establish settlements in various parts of the country. Among the relatives who traveled on were such chiefs as Mwase, who moved into the area called Kasungu, Kaphwiti and Lunda, who settled in the lower Shire valley. As they spread throughout the central and southern part of the country, into eastern Zambia, and into parts of Mozambique, including along the Zambezi River, their language spread too. The dispersion of Kalonga's relatives and the ensuing Chewa diaspora resulted in a proliferation of regional varieties of the language. The distinct names that the regional varieties acquired created the impression of the existence of a multiplicity of ethnic groups. Some of the groups identified themselves by making reference to significant features of their habitat.

Malawi is a country dominated by a huge lake that ranks as the third largest in Africa, after Victoria Nyanza (Lake Victoria) and Lake Tanganyika, and as the 12th largest in the world. As indicated, the word for a large expanse of water in Chichewa is *nyanja*, and the word for tall grass (savanna) is *chipeta*. The people who settled along the lakeshores and along the banks of the Shire River began to call themselves aNyanja, the lake people, and their particular variety of Chichewa was called chiNyanja, or simply Nyanja, the language of the lake people. Those who moved into the interior, the land of tall grass, were called aChipeta, the dwellers of the savanna land. These names began to obscure the nature of the relationship among the people. This was further complicated by the introduction of yet other labels. Thus, the advent of the Portuguese, entering the area from southern Africa in the 17th century, was accompanied by the introduction of new labels. They had been in contact with such ethnic groups as the Xhosa, the Nyika, the Tchangani, etc. These referred to themselves as amaXhosa, amaNyika, amaTchangani, etc. Banda claimed that when the Portuguese encountered the Chewa living in southern Malawi and southern Mozambique, who referred to themselves as aNyanja, they referred to them as amaNyanja (see Banda, 1974–1975). Under the influence of Portuguese phonology, the sound *ny*, a palatal nasal, got velarized to *ng'*. This gave rise to an ethnic group of amaNg'anja, whose language was called chiMang'anja, definitely not distinct from the Nyanja. Meanwhile, the Chewa who had settled around the southern end of Lake Malawi, spreading to the area surrounding Lake Chirwa, encountered another ethnic group, the Yao. The Yao predominated in Mozambique but had flowed into the southeast part of Malawi. The Yao word for a large expanse of water is *nyasa*, and they referred to the Nyanja people as aNyasa. The people had by then come to be grouped into aChewa, aChipeta, amaNg'anja, aNyanja, and aNyasa. The last designation appears to have contributed to British colonialists' eventual designation of the lake as Lake Nyasa, and of the country as Nyasaland. This is the name that the country had until independence in 1964, when the name of Malawi, apparently derived from 'Maravi,' was restored.

The multiplicity of labels under which the Chewa came to be identified was something that received some comment from various scholars. Thus, Young remarks about the language Nyanja that

> it is the language of a people scattered over a large South-east-central African area, the aMaravi, who today live under at least six different names according to the area in which Europeans found them in the closing decades of the last century. And they were more or less on the same ground at least 300 years earlier since the Portuguese records give some of them the same names as they bear to-day. (Young, 1949: 53)

Earlier, Hetherwick had stated that

> On the Shire River they are called Mang'anja, a merely local pronunciation of the word A-Nyanja. Around Lake-Shirwa they are best known by their Yao name A-Nyasa. (Hetherwick, 1901: 15)

Although Chichewa is widely spoken in Southern, eastern, and central Africa, spreading over the landmass that includes Zambia, Malawi, Mozambique, and Zimbabwe, Greenberg does not mention it in his classification of African languages. In the works of Guthrie, Chichewa and Chimang'anja are listed as two dialect variations of Nyanja. He classifies Chichewa as belonging to zone N31b, being identified as the second dialect of the main language.

Chinyanja served as the main linguistic medium for the mass media in Malawi and was taught as a subject in educational institutions at both primary and secondary levels. In 1968, under political pressure from President Banda, a resolution was passed at the annual convention of the Malawi Congress Party, then the ruling and sole political party in Malawi, to have the name of the language officially changed to Chichewa. From that point the language Chinyanja became known as Chichewa in Malawi. Simultaneously, it was elevated to the status of national language. English remained in use as the official language.

The language policy adopted in Malawi that made Chichewa the national language contributed to the promotion of Chichewa through active educational programs, media usage, and other research activities. With the exception of work carried out within the University of Malawi, tied to contributions to, and adaptations of, advances in linguistic theory, the promotion and standardization of Chichewa were placed

under the oversight of the Chichewa Board. The terms of reference of the Chichewa Board included monitoring of proper usage of Chichewa in the media, revising and updating the orthographic conventions, as well as engaging in lexicographic work. The sustained effort over many years to boost the status of Chichewa as the main language resulted in increased functional literacy in that language. Out of a population of around 11 million in Malawi, upwards of 65% have functional literacy or active command of this language.

The political directive that led to the change of name of the language in Malawi, from Chinyanja to Chichewa, did not carry over to the neighboring countries of Zambia and Mozambique. Political factors were definitely relevant. During the period when the language issue was being addressed in Malawi, political relations between Malawi and Zambia reached a nadir. This deserves comment.

Regional Politics and Language Issues

Soon after gaining independence from the United Kingdom in 1964, Malawi had a cabinet crisis. A number of radical political activists with more nationalist fervor broke ranks with Kamuzu Banda, then Prime Minister. These were among the political leaders who had invited Kamuzu Banda to return from his exile in Britain, and subsequently Ghana, to join in, and assume command of, the fight for independence. Following the granting of independence the young radicals got disillusioned with the direction taken by Kamuzu Banda's policies. The policies were seen as aiming to oppress the masses, to practically deify Banda himself as a cult figure to whom the people were to pay homage, to undermine the efforts to promote Pan-Africanism, and to maintain the *status quo*, such that the colonialists would still enjoy the privileges that they had before independence. In brief, Banda's policies brought out the dictatorial tendencies that were eventually to characterize his rule and laid the groundwork for his tyrannical grip over the country's political development. In the revolt that resulted from the rift, the dissident politicians left the country and sought refuge in the neighboring countries of Tanzania and Zambia. This resulted in strained relations between Malawi on the one hand and those other countries on the other.

The situation became aggravated when, around 1967, there was an unsuccessful effort by a group of insurgents under the leadership of Yatuta Chisiza, a dissident politician, to unseat Kamuzu Banda militarily. The military escapade was viewed as having been perpetrated with the connivance or complicity, if not open support, of those neighboring countries. At the minimum, the insurgents seemed to have received logistical support from Zambia (for relevant details see Mchombo, 1998a, 1998b).

The worsening relations between the two countries meant that the policy about language, in this regard relating to change in the name, was not merely viewed as an issue internal to Malawi but, further, as yet another instance of Kamuzu Banda's grandiose scheme to identify the country or region with his cultural and linguistic heritage, a version of Chewa hegemony. As noted by Matiki, "Banda carried this idea of Chewa supremacy a little further by claiming that the dialect spoken by his clan is the best. This is nothing but linguacentrism" (Matiki, 1997: 529). Even if the logic or historical accuracy or factual basis for the name change were to prove impeccably sound and unimpeachable, Zambia was not ready to take hints or, worse, orders, from Malawi. A subsequent dispute concerning the proper borders of the countries, again perpetrated by the Malawi regime around the same time, merely exacerbated an already grave situation. Thus, in Zambia, as well as in Mozambique, the language has always remained as Chinyanja.

In Mozambique Chinyanja is native to 3.3% of a population numbering approximately 11.5 million. In Tete Province it is spoken by 41.7% of a population of 777 426, and it is the first language of 7.2% of the population of Niassa Province, whose population totals 506 974 (see Firmino, 1995). In Zambia, with a population of 9.1 million, Chinyanja is the first language of 16% of the population and is used and/or understood by at least 42% of the population, according to a survey conducted in 1978 (cf. Kashoki, 1978). It is one of the main languages of Zambia, ranking second after Chibemba (Bemba). In fact, out of the 9.1 million people of that country, it is estimated that 36% are Bemba, 18% Nyanja, 15% Tonga, 8% Barotze, and the remainder consisting of other ethnic groups including the Mombwe, the Tumbuka, and the Northwestern peoples (see Kalipeni, 1996). The figures show that at least six million people are fluent in Chinyanja.

The Ascendancy of Chinyanja

A recurrent joke in linguistics courses about the distinction between language and dialect is the quip that a language is 'a dialect with an army and a navy.' The rise of Chichewa in Malawi was intimately connected to the tenure of Kamuzu Banda, a Chewa, as president of Malawi. With altered political dispensation through the shift to democratic practice, and Banda's subsequent demise, Chichewa effectively lost the 'army and navy' that protected it from the status of dialect. Without formally or openly introducing a

new language policy, Malawian scholars have felt it prudent to fall in line with the other countries in the region by restoring the name of Chinyanja to the language. This restoration of Chinyanja to its former status goes beyond mere efforts to promote regional linguistic harmonization. Within Malawi the national language policy adversely affected the other languages. Once again, as noted by Matiki, "the change of name [from Chinyanja to Chichewa] angered some people because there was no justification in changing the name other than the fact that President Banda was an ethnic Chewa" (1997: 527). Thus, the other ethnic groups in the country felt alienated, more so given the identification of Chichewa with political power and the relegation of their languages to relative obscurity (cf. Kishindo, 1994). The political transition to democratic practice and the departure of Kamuzu Banda from the political helm provided opportune occasion for implementation of more equitable access to political participation and the recognition of the cultural and linguistic heritage of the various segments of the nation. Kamuzu Banda's departure from the political scene was accompanied by the ascendancy of Bakili Muluzi, a Yao, as the second president of a democratic Malawi. Inevitably, the political changes witnessed shifting fortunes for Chichewa.

On Reverting to the Name of Chinyanja

Although use of the label Chichewa is likely to remain, there is systematic diminution of its former status. Thus, the Chichewa Board was subsequently dissolved and, in 1996, the Center for Language Studies (CLS), with a broader scope of activities, was established to replace it. The center is affiliated to the University of Malawi, stressing its new mandate as a locus of research and scholarship, not as an organ of political ideology or an instrument of political hegemony. The activities carried out under the auspices of the CLS have included concerted efforts to document and provide linguistic descriptions of some of the endangered languages in Malawi.

Further, the erstwhile Department of Chichewa and Linguistics at the University of Malawi, pioneered by the present author, under political directive from President Banda to the University of Malawi to contribute to the enhancement of Chichewa, was renamed the Department of African Languages and Linguistics, thereby degrading further the profile of Chichewa.

The 'politically correct' stance of diminishing the profile of Chichewa in the university through the removal of direct reference to it in the name of the department, together with the establishment of the CLS, should not, however, be (mis)construed as indicating a real diminution in linguistic work on it. Given the historical circumstances which account for the preponderance of the available trained linguists working on Chichewa, and the headstart Chichewa was given in getting material prepared for educational and other purposes, it will continue to function in the capacity of the major language of the country. Of some significance, at least to public perception, is the recent introduction of radio news bulletins in the other languages such as Chilomwe (Lomwe), Chiyao (Yao), Chitumbuka (Tumbuka), Chitonga (Tonga), and Chisena (Malawi Sena). The news bulletins have served to increase people's awareness of these other Malawian languages, subtly contributing to the subjection of Chichewa to competition.

There are grounds for the restoration of Chinyanja as the main language. These include the literary tradition that Chinyanja has enjoyed (see Made *et al.*, 1976). The description of Chinyanja goes back to at least 1875; the first significant work can be traced to Alexander Riddel's publication in 1880 of *A grammar of Chinyanja as spoken at Lake Nyasa, with Chinyanja-English vocabulary.* This work, while not linguistically very significant, was followed in 1891 with the publication of George Henry's *A grammar of Chinyanja: a language spoken in British Central Africa on and near the shores of Lake Nyasa*. This was more comprehensive than the work by Riddel. In 1892 David Scott's *A cyclopaedic dictionary of the Mang'anja language spoken in British Central Africa* appeared, a work that was later to be revised and enlarged by Alexander Hetherwick in 1929 as *Dictionary of the Nyanja language*. This still remains an authoritative dictionary of the language. Previously, in 1901, Hetherwick had produced *A practical manual for the Nyanja language*.

These descriptions of Chinyanja and the functional utility that the language enjoyed underscored its legitimacy to the status of a major language or lingua franca. The subsequent adoption of the colonialists' language policy, which recognized the position of Chinyanja in Central Africa, especially in Malawi, eliminated further detractions from its status. The establishment of the colonial administration in Malawi at the turn of the 20th century provided extra impetus to the promotion of Chinyanja. This led to the appearance of more works on Chinyanja and the emergence of more literary works and newspapers, such as *Msimbi*, a weekly Chinyanja newspaper that flourished for several years from 1951.

As Chinyanja gets rehabilitated, and some recent publications such as dictionaries now bear that name instead of Chichewa, the latter still remains

undeniably the most familiar label for the language that is spoken and understood by more than half the population of Malawi. The reversion to the label of Chinyanja, just like the prior change to Chichewa, may lack a linguistic basis but it definitely fulfills political objectives.

Linguistic Aspects of Chinyanja

Chinyanja manifests typical aspects of the linguistic structure of Bantu languages. Its nominal system comprises a number of gender classes that are involved in the agreement patterning of the language, characteristic of Bantu languages. Thus, nominal modifiers agree with the head noun in the relevant features of gender and number, as will be illustrated below.

In its verbal structure, Chinyanja, just like other Bantu languages, displays an elaborate agglutinative structure. The verb comprises a verb root or radical, to which suffixes or extensions are added to form the verb stem (cf. Guthrie, 1962). The extensions affect argument structure or the number of expressible nominal arguments that the stem can support. The verb stem also has proclitics which encode such syntactically oriented information as negation, tense/aspect, subject and object markers, modals, conditional markers, directional markers, etc. (cf. Mchombo, 2004).

Chinyanja is also a tonal language, displaying features of lexical and grammatical tone. It has two tone levels, high (H) and low (L). Contour tones are attested but result from a combination of these tone levels, usually on long syllables (Mtenje, 1986). In its segmental phonology, Chinyanja has a basic organization of five vowel phonemes. The verb stem, i.e., the domain comprising the verb root and the suffixes changing argument structure, is also the domain of vowel harmony. In its syllable structure, Chinyanja has the basic CV structure common in Bantu (Mtenje, 1980).

Classification of Nouns

The nominal morphology of Chinyanja displays the paradigmatic case of nouns maintaining, at the minimum, a bimorphemic structure, which consists in a nominal prefix and a nominal stem. The prefix encodes grammatically relevant information of gender (natural) and number, involved in agreement between the nouns and other grammatical classes in construction with them. This is illustrated by the following:

m-lenje 'hunter'	a-lenje 'hunters'
chi-soti 'hat'	zi-soti 'hats'
m-kóndo 'spear'	mi-kóndo 'spears'

A lingering perennial question relates to the semantic or cognitive basis for the classification of nouns. A definitive response to the question remains forthcoming. Noun modifiers are marked for agreement with the class features of the head noun, and these features are also reflected in the subject marker (SM) and object marker (OM) in the verbal morphology. This can be illustrated by the following:

(1a) chi-soti ch-ángá lch-á-tsópanó
7-hat 7SM-my 7SM-ASSOC-now
chi-ja chí-ma-sangaláts-á a-lenje
7SM-REL.PRO 7SM-HABIT-please-FV 2-hunters
'that new hat of mine pleases hunters'

(1b) m-kóndó w-angá w-á-tsópanó
3-spear 3SM-my 3SM-ASSOC-now
u-ja ú-ma-sangaláts-á a-lenje
3SM-REL.PRO 3SM-HABIT-please-FV 2-hunters
'that new spear of mine pleases hunters'

In these sentences, the words in construction with the nouns are marked for agreement with that head noun. (The actual agreement markers in these examples are *chi* and *u*. The *i* vowel in *chi* is elided when followed by a vowel, and the *u* is replaced by the glide *w* in a similar environment.) Chinyanja is a head-initial language. Within the noun phrase the head noun precedes its modifiers. The formal patterns that mark singular and plural number are traditionally identified by a numbering system, now virtually standard in Bantu linguistics (Bleek, 1862–1869). Consider the following data:

(2a)	m-nyamäta 'boy'	a-nyamäta 'boys'
	m-lenje 'hunter'	a-lenje 'hunters'
	m-kázi 'woman'	a-kázi 'women'
(2b)	m-kóndo 'spear'	mi-kóndo 'spears'
	mü-nda 'garden'	mï-nda 'gardens'
	m-kángo 'lion'	mi-kángo 'lions'
(2c)	tsamba 'leaf'	ma-samba 'leaves'
	duwa 'flower'	ma-luwa 'flowers'
	phanga 'cave'	ma-panga 'caves'
(2d)	chi-sa 'nest'	zi-sa 'nests'
	chi-tösi 'chicken dropping'	zi-tösi 'chicken droppings'
	chi-pútu 'grass stubble'	zi-pútu 'grass stubble'

These classes show part of the range of noun classification that is characteristic of Bantu languages. In the examples above, the singular forms of the first group above, dominated by nouns that denote animate things, constitutes Class 1, and its plural counterpart is Class 2. Of course, not all animate things are in this class. In fact it does also include some inanimate objects. The groups in (2b), (2c), and (2d) constitute Classes 3, 4, 5, 6, 7, and 8 respectively. The odd numbers indicate the singular forms and the even numbers their plural counterparts. This runs on to

Classes 5, 6, 7, and 8. There is a further class, 1a. This class consists of nouns whose agreement patterns are those of Class 1 but whose nouns lack the *m(u)* prefix found in the Class 1 nouns. The plural of such nouns is indicated by prefixing *a* to the word. For instance, the noun *kalúlu* 'hare', whose plural is *akalúlu*, typifies this class. Each of these classes has a specific class marker and a specific agreement marker. Beginning with Class 2, the agreement markers are respectively *a*, *u*, *i*, *li*, *a*, *chi*, and *zi*. Class 1 has the agreement markers *mu* (or syllabic *m*), *u*, and *a*, depending on the category of the modifier. Consider the following:

(3) m-lenje m-módzi a-na-bwélá ndí mí-kóndo
1-hunter 1SM-one 1SM-PAST-come-FV with 4-spears
'one hunter came with spears'

Here, the numeral *módzi* 'one' is marked with the agreement marker *m* but the verb has *a* for the subject marker. The *u* is used with demonstratives and when the segment that follows is a vowel. This seems to apply to most cases regardless of whether the vowel in question is a tense/aspect marker, an associative marker, or part of a stem, such as with possessives. Consider the following:

(4) m-lenje w-ánú u-ja w-á
1-hunter 1SM-your 11SM-that SM-ASSOC
nthábwala w-a-thyol-a mi-kóndo
10-humor 1SM-PERF-break-FV 4-spears
'that humorous hunter of yours has broken the spears'

In this sentence, the glide *w* replaces *u* when a vowel follows regardless of the function associated with that vowel.

Although most of the nouns are bimorphemic, there are a number of cases where a further prefix, marking either diminution or augmentation, is added to an already prefixed noun. This is shown in the following:

(5) ka-m-lenje k-ánú ka-ja k-á
12-1-hunter 12SM-your 12SM-that 12-ASSOC
nthábwala k-a-thyol-a ti-mi-kóndo
10-humor 12SM-PERF-break-FV 13–4-spears
'that small humorous hunter of yours has broken the tiny spears'

In this sentence, the preprefixes *ka* for singular and *ti* for plural get attached to nouns to convey the sense of diminutive size. These preprefixes then control the agreement patterns (cf. Bresnan and Mchombo, 1995), providing the rationale for regarding them as governing separate noun classes. One significant point to be made is that locatives also control agreement patterns. Consider the following:

Table 1 Full range of noun classes in Chinyanja

Classes		*Prefixes*		*Subject marker*		*Object marker*	
SG	*PL*	*SG*	*PL*	*SG*	*PL*	*SG*	*PL*
1	2	m(u)-	a-	a-	a-	m(u)	wa
3	4	m(u)-	mi-	u-	i-	u	i
5	6	*li-	ma-	li-	a-	li	wa
7	8	chi-	zi-	chi-	zi-	chi	zi
9	10	*N-	*N-	i-	zi-	i	zi
12	13	ka-	ti-	ka-	ti-	ka	ti
14	6	u-	ma-	u-	a-	u	wa
15		ku-	ku-	ku-			
16		pa-	pa-	pa-			
17		ku-	ku-	ku-			
18		m(u)-	m(u)-	m(u)-			

(6) ku mudzi kw-ánu kú-ma-sangaláts-á
17-at 3-village 17SM-your 17-HABIT-please-FV
alëndo
2-visitors
'your village [i.e., the location] pleases visitors'

This gives such locatives the appearance of being class markers, giving rise to the view that in Chinyanja locatives are not really prepositions that mark grammatical case but, rather, class markers (for some discussion, see Bresnan, 1991, 1994).

The full range of noun classes in Chinyanja, together with their restive subject and object markers, is given in Table 1. Some of the classes have prefixes that are starred. These classes consist of nouns that, normally, lack the indicated prefix in the noun morphology. Samples of Class 5 nouns are provided above. Most of the nouns in Classes 9 and 10 begin with a nasal but there are no overt changes in their morphological composition that correlate with number. The number distinction is reflected in the agreement markers rather than in the overt form of the noun. Examples of Class 9/10 nouns are *nyümba* 'house(s)', *nthenga* 'feather(s)', *mphîni* 'tattoo(s)', *nkhôndo* 'war'. Class 15 consists of infinitive verbs. The infinitive marker *ku-* regulates the agreement patterns, just like the diminutives (Classes 12 and 13) and locatives. The infinitives are thus regarded as constituting a separate class although, just as with the locatives, there are no nouns that are peculiar to this class. There are minor exceptions to locatives. These have to do with such words as *pansi* 'down', *kunsi* 'underneath,' *panja* 'outside of a place', *kunja* '(the general) outside', *pano* 'here (at this spot)', *kuno* 'here (hereabouts)', *muno* 'in here'. With these, the locative prefixes *pa*, *ku*, and *mu* are attached to the stems *-nsi*, *-nja*, and *-no*, which are bound. The

agreement pattern regulated by the infinitive marker *ku-* is exemplified by the following:

(7) ku-ímbá kw-anú kú-ma-sangaláts-á
15INF-sing 15SM-your 15SM-HABIT-please-FV
a-lenje
2-hunters
'your singing pleases hunters'

O'Rahilly, Thomas Francis (1883–1953)

K A Klar, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Thomas Francis O'Rahilly's interests spanned the breadth of Irish (Gaelic) language, literature, and history, although successive periods of his career were marked by different predominant themes. Prior to the commencement of his formal academic career, he founded *Gadelica: A Journal of Modern Irish Studies;* it ran to just one issue, but featured articles by many of the most prominent figures in Irish language and literature studies. O'Rahilly held successive posts at Trinity College Dublin (1919–1929), University College Cork (1929–1935), University College Dublin (1935–1941), and the Dublin Institute of Advanced Studies (1940–1947). He became director of the Dublin Institute in 1941.

His early scholarly productions included the editing of volumes of Irish epigrams and proverbs, and two anthologies of traditional poetry (*Dánta grádha* in 1926; *Measgra dánta* in 1927). His major linguistic contribution, *Irish dialects, past and present*, appeared in 1932. In his later years, he focused mainly on the history and foundational mythology of Ireland; the somewhat controversial *Early Irish history and mythology* (1946) was a compendium of his work in this field. In the same year he founded the journal *Celtica* and edited its first volume, which was marked by an eclectic mix of linguistic, literary, and historical subjects reminiscent of the scope of the earlier *Gadelica* venture. *Celtica* continues to publish to this day.

In *Irish Dialects*, O'Rahilly compared the Irish dialect situation in the early 1900s to that of English in the 14th century in that there was no standard

language and great dialect differences. In contrast, however, the Irish language had since the mid-18th century, been increasingly losing ground as the primary language of everyday life; both the professional literary classes and later the English speakers whose party controlled Ireland despised the language of the common people and actively discouraged its use. O'Rahilly noted that at the time of writing "the Irish language has died out in five-sixths of the country," and lamented that "the monoglot Irish-speaker seems doomed to extinction." This situation made the collection of what information remained about Irish dialects "a task of extreme urgency." O'Rahilly collected together all the resources, both literary and oral, from the entire history of Irish literature, and including his own first-hand field research, to make his survey (which includes excursions into Scottish Gaelic and Manx). Although he believed that his resources were limited, his close analysis led to a precise delineation of historical Irish into Northern and Southern dialects, each of which was further subdivided in two main subdialects. As he assembled sources, he produced the *Catalogue of Irish* manuscripts *in the Royal Irish Academy.*

In his observations about the relationship between social status and language disappearance, O'Rahilly anticipated the later 20th century concerns about "language death." His study stands as an early model of what linguists can and should do to both document endangered languages and encourage survival of speech traditions that are threatened by overwhelming social, economic, and political circumstances. In stressing the urgency of his task, his study also serves as a warning as to how quickly a population can go from being virtually monolingual to being a minority language in constant danger of extinction.

Oral Traditions and Spoken Discourse

A Varvaro, Università di Napoli Federico II, Napoli, Italy

The Problems with Oral Traditions

In our society, the idea that literature exists only in the written form has for a long time meant a total devaluation of the oral tradition. It has led to the conviction that style and rhetoric are characteristics only of written discourse. This idea has remained deep-seated in public opinion even after Romanticism prompted the revaluation of some types of oral (or pseudo-oral) literature. Yet, it is clear to all that until recent times, with the expansion of compulsory schooling and above all the media, only a tiny percentage of people, concentrated in a small number of literate societies, could master the written form of expression. In the history of humankind, this form of expression is the exception and not the rule.

In every literary tradition of which we are aware, starting with those of the Levant and ancient Greece, the oldest known documents testify to the existence of at least three oral practices that can be fully classed as literature: lyric poetry, narrative poetry, and stories. Modern research in the field confirms that there is practically no human society that does not have an oral tradition, even if the society is completely illiterate. In contrast, we know of societies that despite being literate prefer not to rely on the written word for their most significant traditions, as Caesar observed was the case in the Gaul of the Druids:

> Neque fas esse existimant ea litteris mandare, cum in reliquis fere rebus, publicis privatisque rationibus, graecis litteris utantur. 'And they do not think it proper to commit these utterances [i.e., great number of verses] to writing, although in almost all other matters, and in their public and private accounts, they make use of Greek letters.'

Many oral societies have literary traditions that have an exceptionally complex structure and that are surprisingly prolific. The overview provided 70 years ago in a work that has become definitive, despite being for the most part a compilation of

O

Object-Dependent Thoughts

S Crawford, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Some of our thoughts involve reference to particular individual entities. Philosophers call these kinds of thoughts 'singular thoughts.' *Russell was a great philosopher*, *you're standing on my foot*, *I'm tired*, *that raccoon got into my garbage last night* – these are all singular thoughts because each involves reference to a particular thing: Russell, you, me, and a certain raccoon, respectively. As these examples indicate, singular thoughts are usually expressed by sentences containing proper names (e.g., 'Russell'), indexicals (e.g., 'you' and 'I'), and demonstrative expressions (e.g., 'that raccoon').

Singular Thoughts as Object Dependent

Some philosophers maintain that singular thoughts are *object dependent*, by which they mean that the intentional content of the thought essentially involves the object that it is about, in the sense that the thought content would not be available to a thinker were the object not to exist. More precisely, a singular thought is object dependent just in case its content is such that (1) its existence depends on the existence of the object thought about, and (2) its identity depends on the identity of the object thought about. For example, consider the thought *that raccoon got into my garbage last night*, had by me while spying a particular raccoon skulking in my backyard. According to the doctrine of object dependence, if, counterfactually, no raccoon had in fact been there to be singled out by me, owing perhaps to my delusional or hallucinatory state of mind – let us call this the "empty possibility" – then there would have been no singular thought content for me to entertain. Consequently, my psychological condition in this situation would be different from what it is in the actual situation. Moreover, if, counterfactually, my thought had singled out a qualitatively indistinguishable but numerically different raccoon instead – call this the "duplicate possibility" – then the resulting thought would have had a different content from the content that my thought had in the actual situation. Again, my overall psychological state in this duplicate possibility is different from what it actually is. The implication here for linguistic meaning is that the meaning of sentences containing genuine singular terms (e.g., proper names, indexicals, and demonstrative expressions) depends on the singular terms in question successfully referring to objects. On this view, nonfictional sentences containing nonreferring singular terms, such as empty or bearerless names, are meaningless, in the sense that they fail to express any thoughts.

The doctrine of object dependence is a species of the more general doctrine of *externalism* about thought content, according to which some states of mind are such that we can be in them only if we bear certain appropriate relations to other things in our environment, and thus is opposed to *internalism* about the mind, according to which the contents of our thoughts are never dependent on any relations between us and other things in our environment. (Some philosophers, such as Burge [1982], accept the general doctrine of externalism but reject object dependence.)

Epistemological Consequences of Object-Dependence

It is controversial which, if any, singular thoughts are object dependent. Arguably, first-person thoughts expressed with the indexical 'I' are object dependent: it seems obvious that if I did not exist, then the thought that I now express with the sentence *I'm tired* could not exist; moreover, no one else could have had the very same thought. But the thesis that singular thoughts expressed with proper names and demonstratives are object dependent has seemed paradoxical to some philosophers. For when the idea of object dependence is applied to these other types of singular thoughts, it runs up against a strongly held intuition about the nature of thought content, namely, that we have a kind of direct, noninferential knowledge of the contents of our thoughts, in the sense that we know, just by thinking, whether we are having a thought and, moreover, what thought we are having.

The doctrine of object dependence seems to contravene this intuition about the epistemology of thought.

For, first of all, condition (1) above allows the possibility that a thinker could suffer the illusion of entertaining a thought when he was not in fact doing so. If, unbeknown to me, I am in what we have been calling an empty possibility and am hallucinating a raccoon rather than actually seeing one, it may seem to me that I am having a singular thought, which I might try to express with the sentence *that raccoon got into my garbage last night*, even though I am not. But is this kind of cognitive illusion really possible? It is very tempting to think, against this, that if it seems to me as if I am having a thought with a certain content, then I am. Perhaps I might be mistaken about which object, if any, my thought is about – but how could I be mistaken about whether I was even thinking a thought at all?

Condition (2) has also seemed problematic. Consider what we have called the duplicate counterfactual possibility, in which I see a different raccoon, qualitatively indistinguishable from the one I actually see, and think *that raccoon got into my garbage last night*. In such a case, everything will seem the same to me: the duplicate raccoon does not appear to affect my conscious awareness in any way different from how the actual raccoon affects it. But is not subjective indistinguishability the criterion for sameness and difference of thought content? Opponents of object dependence argue that in order for there to be a genuinely psychological or mental difference between the two cases, this difference must impinge on my conscious awareness in some way. The object-dependent theorist denies this, arguing that it is the product of a mistaken internalist picture of the mind, a picture that the object-dependent theorist urges us to reject in favor of an externalist view. The debate between object-dependent theorists and their opponents is thus linked to a certain extent to the larger debate between internalism and externalism about thought content.

The Central Motivation for Object Dependence

A number of different considerations have been advanced in favor of an object-dependent conception of singular thought, and many involve a synthesis of key ideas of Frege and Russell (Evans, 1982; McDowell, 1977, 1984, 1986; McCulloch, 1989). Advocates of this form of object dependence are often labeled 'neo-Fregeans,' which can be confusing, because object-dependent singular thoughts are also often called 'Russellian thoughts,' so one needs to be aware of differing terminology here.

Perhaps the best way to appreciate the object-dependent theorists' point of view is to begin by noting that they do countenance thoughts that in a certain sense concern particular individuals but that would be available to a thinker were those individuals not to exist. Moreover, there is a straightforward sense in which the contents of these kinds of thoughts would remain unaffected were duplicate objects substituted for the actual ones. Calling these kinds of thoughts object-*in*dependent thoughts, we can say that although they concern particulars, the relation between their contents and their objects is much less direct or intimate than the relation between the contents and objects of object-dependent thoughts (the idea goes back to Russell's seminal distinction [1910–1911] between knowledge by description and knowledge by acquaintance).

The most obvious examples of object-independent thoughts are thoughts that involve definite description concepts, thoughts of the form *the F is G*. Consider the thought *the first man on the moon was an American*. As it happens, this thought is about Neil Armstrong because he was in fact the first man on the moon. But consider now the empty possibility in which the lunar landing was a hoax and the definite description *the first man on the moon* fails to designate anything. The object-dependent theorist holds that even though the thought fails to single out any actual object in the world, the thought still has a content, a content expressed, in part, by the definite description. Similarly, consider the duplicate possibility, in which Neil Armstrong's identical twin is the first man on the moon. Despite the thought's picking out a different man, the content of the thought remains the same – again, that expressed (in part) by the definite description *the first man on the moon*. The crucial point here is that the intentional content of the thought can be specified independently of the object, if any, that it is about.

The object-dependent theorist's idea is this. Thought content is essentially representational: it represents the world as being a certain way; it lays down conditions that the world must meet in order for the thought to be true. That is to say, the content of a thought determines its truth conditions. In the case of a thought employing a definite description concept *the F* (a descriptive thought, for short), the thinker knows what those conditions are without knowing which object, if any, the thought concerns. If I say to you *the first man on the moon was American*, it is not necessary for you to know which object is the first man on the moon, nor even that there is such an object, in order for you to understand what I have said, in order for you to "grasp" the thought I expressed with this sentence. So long as

you understand all the words in the sentence and their mode of combination, you know exactly how the world is represented as being; you know what the thought is "saying" about reality. In other words, you know that the thought is true just in case there is a unique man who was first on the moon and who was American. It does not matter who this man happens to be – Neil Armstrong, his identical twin, or Buzz Aldrin. So long as there is such a man, the thought is true; and if there is no such man – either because no man at all has ever been on the moon or because more than one man stepped onto the moon at exactly the same time – then the thought is false. The representational content of a descriptive thought is thus independent of any object that the content might be about. The truth conditions make no reference to any man in particular.

When it comes to singular thoughts, however, the object-dependent theorist maintains that their representational content is not independent of any object the content is about. On the contrary, the content requires that a certain particular object be picked out. In order to understand or grasp the thought in question, one must know which particular object this is. Consider the foregoing example of a singular thought: *that raccoon got into my garbage last night*, based on my visual experience of a particular raccoon in my backyard (these kinds of singular thoughts are sometimes called 'perceptual demonstrative thoughts'). Now, in having this thought, I am representing the world in a certain way. What way is this exactly? Well, I am not representing the world as merely containing a raccoon that got into my garbage last night, whichever raccoon that might be. The way I am representing the world as being involves that very raccoon. My thought is true just in case that raccoon (the very one I saw) got into my garbage last night; and in order for you to have this thought too, you need to know which particular raccoon is singled out by my perceptual demonstrative 'that raccoon.' Contrast this with the very different case in which I think the descriptive thought *the cleverest and boldest raccoon in the neighborhood got into my garbage last night*. All that it takes for this thought to be true is for there to be a unique raccoon, who is cleverer and bolder than all the rest and who got into my garbage – and you can grasp this thought without knowing which raccoon, if any, that was. If it turns out that there was no such raccoon, then my thought is straightforwardly false. But the truth conditions for my perceptual demonstrative thought make essential reference to the very object it is about. The truth or falsity of this thought of mine turns on the condition of a particular raccoon, namely, that raccoon – so that if there is no such creature, if (say) I am hallucinating, there is nothing in the world to count as my thought being true or false. Consequently, in this empty possibility, my mental episode, whatever exactly its nature, has no truth conditions (for, to repeat, there is nothing *of which* I have judged to have a certain property; nor have I made the mere existential claim that there is *an* object with a certain property). Since thought content is essentially truth conditional, according to the object-dependent theorist, I have not in fact had a singular thought at all, only the illusion of one. Whether considerations like these in favor of object dependence apply equally to other kinds of singular thoughts, such as those expressed with proper names and indexicals (other than 'I'), is a further question.

Criticisms and Rivals

Various criticisms have been leveled at the object-dependent conception of singular thought. Some of these arise from problems that the conception inherits from the general doctrine of externalism, such as its apparent conflict with certain features of self-knowledge (Davies, 1998). Three issues, however, stand out with respect to object dependence in particular.

The first is the question of what is going on, psychologically speaking, in the minds of deluded subjects in empty possibilities who suffer the illusion of entertaining singular thoughts. Their minds are not phenomenological blanks, after all; yet, according to the object-dependent theorist, they are not filled with any singular thoughts. Are such deluded subjects having any thoughts at all? If so, what kinds of thoughts are they having?

The second issue is closely related to the first and concerns the commonsense psychological explanation of the actions of deluded subjects. Normally, we explain agents' actions – my charging into the backyard, say – by attributing singular thoughts to them – the belief that that raccoon got into my garbage last night, for example. But now consider my deluded duplicate who, after hallucinating a raccoon in the empty possibility, engages in the very same type of behavior of charging into the backyard. According to the object-dependent theorist, my duplicate here has no singular thought; that is, he has no belief the content of which is *that raccoon got into my garbage last night*. But, although he is hallucinating, his action is perfectly rational and so is presumably psychologically explicable by ordinary commonsense standards. But how do we so explain his behavior without attributing a singular thought to him (McDowell, 1977; Segal, 1989)? Moreover, if we can explain his behavior without attributing a singular thought to him, then why can we not do the same with me in the

actual situation? But if we can do this with me too, then it looks as if the ascription of object-dependent singular thoughts is 'psychologically redundant' – and that allegedly calls into question their very existence (Noonan, 1986, 1991; Segal, 1989).

The third issue, perhaps the most serious, is that there are powerful rival object-independent conceptions of singular thought, which are free of many of the problems that beset object-dependent theories. There tend to be two different kinds of alternative conceptions.

The first of these conceptions attempts to analyze singular thought content in wholly general or descriptive terms, in such a way that the same content can exist in duplicate and empty possibilities, in the manner of thoughts involving definite description concepts, discussed earlier (Schiffer, 1978; Searle, 1983, 1991; Blackburn, 1984: chapter 9). For example, we might try to analyze the content of the demonstrative expression *that raccoon* as equivalent to the content of the definite description *the raccoon I am seeing now* or *the raccoon causing this visual experience*.

The second approach opposes this kind of descriptive reduction and maintains a genuinely singular conception of singular thought but argues that a distinction between irreducibly singular (or "*de re*") content and object can still be drawn, again, in such a way that, as with the first alternative, the same singular content can exist in both duplicate and empty possibilities (Burge, 1977, 1982, 1983, 1991; Bach, 1987; Segal, 1989). This approach exploits an analogy between the semantics of sentences containing demonstratives and pronouns (*this is red*, *she is tall*) and the semantics of the open sentences of a logical system (*x is red*, *x is tall*) – namely, that both kinds of sentences are true or false only under an assignment of values to the demonstratives, pronouns, and free variables in question. The proposal is to treat a sentence such as *that is a raccoon* as like a predicate, or open sentence in the logician's sense, and to think of it as expressing a single content (a "propositionally incomplete" content) that is mentally applied, in different situations, to different objects, and even, in some situations, to no object at all.

These two alternatives each face their own difficulties, however. The first alternative seems to overintellectualize thinking. When I think *that raccoon got into my garbage last night*, I do not appear to be thinking about myself or the present moment or about causation or my own visual experiences, and even if I were doing so in a philosophical mood, it does not seem necessary for a creature to have such sophisticated concepts in order for it to have singular thoughts (McDowell, 1991; Burge, 1991; Searle, 1991). As for the second alternative, it is not clear to what extent it departs from the intuitive principle that thought content is fully representational in the sense of always determining truth conditions. For in the empty counterfactual possibility, in which I hallucinate a raccoon, no value will be assigned to the demonstrative concept in my thought (*that raccoon*), and hence no truth conditions for the overall thought will be determined. The advocates of this second alternative approach thus seem committed to the view that I can have thoughts that possess no truth conditions, something that may give us pause.

Objectivity in Moral Discourse

M Timmons, University of Arizona, Tucson, AZ, USA

Does moral discourse purport to be objective? If so, can its objectivist pretensions be justified? Roughly speaking, to say that some form of discourse is objective is to say that there is a single set of truths about whatever subject matter the discourse is about. We can make this rough characterization more precise by formulating a number of related theses – objectivity theses – that collectively capture this idea of objectivity:

Cognitivism: Declarative sentences of the discourse in question are used by speakers to make genuine assertions and function mainly to express the speaker's beliefs. Given that (sincere) belief and assertion aim at representing what is true, such sentences are capable of being true or false.

Truth: Some affirmative sentences of the discourse are true.

Independence: What makes some sentence of the discourse true is that it corresponds to some fact – where the existence and nature of the specific fact to which the sentence corresponds is independent of the attitudes and beliefs that individuals and groups have toward the fact in question. It is common to use the word 'stance' to refer to the beliefs and attitudes of individuals and groups, so using this terminology we may express the independence thesis by saying that for the discourse in question there is a stance-independent reality (realm of facts) that the discourse is about, and the facts comprising that reality are what make certain sentences of that discourse true.

Convergence: Ideally, use of the proper methods of inquiry (which may differ from discourse to discourse) may be expected to lead individuals (at least under suitably ideal conditions) to converge in a great many of their judgments about the subject matter of the discourse in question.

Discourse satisfying these four theses involves sentences that are (or may be) objectively true and hence we may say that the discourse itself is objective. Of course, it is possible for some realm of discourse to feature claims that **purport** to be objectively true but fail to be so because one or more of the above theses fail to hold in relation to the discourse in question – a possibility to which we shall return below.

Moral objectivism, then, at least as it is commonly understood by philosophers, is the view that all four theses hold in relation to moral discourse: not only does moral discourse purport to be objective, it satisfies the objectivity requirements in question and thus some moral judgments are objectively true. Sometimes this is put by saying that there is a single true morality. As we shall see, some philosophers have denied one or more of the four theses in relation to moral discourse and thus denied that morality is objective.

Determining whether moral objectivism is correct requires an examination of fundamental philosophical questions about the meaning, truth, and justification of moral judgments – questions central to that branch of ethics called 'meta-ethics.' But it also requires an examination of the very notion of objectivity. And here we find two models of objectivity. One of them is inspired by discourse about the physical world

Objectivity in Moral Discourse

M Timmons, University of Arizona, Tucson, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Does moral discourse purport to be objective? If so, can its objectivist pretensions be justified? Roughly speaking, to say that some form of discourse is objective is to say that there is a single set of truths about whatever subject matter the discourse is about. We can make this rough characterization more precise by formulating a number of related theses – objectivity theses – that collectively capture this idea of objectivity:

Cognitivism: Declarative sentences of the discourse in question are used by speakers to make genuine assertions and function mainly to express the speaker's beliefs. Given that (sincere) belief and assertion aim at representing what is true, such sentences are capable of being true or false.

Truth: Some affirmative sentences of the discourse are true.

Independence: What makes some sentence of the discourse true is that it corresponds to some fact – where the existence and nature of the specific fact to which the sentence corresponds is independent of the attitudes and beliefs that individuals and groups have toward the fact in question. It is common to use the word 'stance' to refer to the beliefs and attitudes of individuals and groups, so using this terminology we may express the independence thesis by saying that for the discourse in question there is a stance-independent reality (realm of facts) that the discourse is about, and the facts comprising that reality are what make certain sentences of that discourse true.

Convergence: Ideally, use of the proper methods of inquiry (which may differ from discourse to discourse) may be expected to lead individuals (at least under suitably ideal conditions) to converge in a great many of their judgments about the subject matter of the discourse in question.

Discourse satisfying these four theses involves sentences that are (or may be) objectively true and hence we may say that the discourse itself is objective. Of course, it is possible for some realm of discourse to feature claims that **purport** to be objectively true but fail to be so because one or more of the above theses fail to hold in relation to the discourse in question – a possibility to which we shall return below.

Moral objectivism, then, at least as it is commonly understood by philosophers, is the view that all four theses hold in relation to moral discourse: not only does moral discourse purport to be objective, it satisfies the objectivity requirements in question and thus some moral judgments are objectively true. Sometimes this is put by saying that there is a single true morality. As we shall see, some philosophers have denied one or more of the four theses in relation to moral discourse and thus denied that morality is objective.

Determining whether moral objectivism is correct requires an examination of fundamental philosophical questions about the meaning, truth, and justification of moral judgments – questions central to that branch of ethics called 'meta-ethics.' But it also requires an examination of the very notion of objectivity. And here we find two models of objectivity. One of them is inspired by discourse about the physical world

(including ordinary nonscientific discourse about the world as well as scientific discourse) and which I will refer to as the model of 'ontological objectivity' – so called because the central idea is that there is an ontological realm of 'really' existing objects and properties that sentences from a particular discourse purport to be about and which serve to make true certain of those sentences. An alternate, more modest form of objectivity, which I will call 'methodological objectivity,' is less focused on matters of ontology and more focused on methods of reasoning that govern the discourse in question.

In what follows, we begin with a brief characterization of the ontological model of objectivity and then proceed in the next four sections to consider some of the evidence for and controversy about whether moral discourse is ontologically objective. After reviewing the pros and cons of the claim that moral discourse is ontologically objective, we turn to the second model of objectivity – a model that promises to make sense of objectivity without ontology.

Ontological Objectivity

In meta-ethical discussion over the objectivity of moral discourse, discourse about ordinary commonsense objects and their properties as well as scientific discourse – often referred to as descriptive discourse – is taken to be paradigmatic of objective discourse. Roughly, the idea is that descriptive discourse is (or at least purports to be) about a realm of objects and properties in certain combinations (facts) whose nature and existence is independent of our beliefs, conventions, attitudes, and other mental stances we might take toward those facts. Here, the emphasis is on considerations of ontology – on what exists – hence the label 'ontological objectivity.' Moreover, the ontological objectivist typically embraces a strong form of the independence thesis, viz.,

> What makes some sentence true is that it corresponds to some sort of stance-independent fact – where the existence and nature of the fact in question is independent of the actual **and ideal** stances of individuals or groups.

The significance of this thesis of strong independence (SI) will emerge later on when we turn to methodological objectivity.

So the model of ontological objectivity (using descriptive discourse about objects and properties in the world as an example) clearly involves the first three objectivity theses: descriptive discourse serves to express beliefs (cognitivism), some of which are true (truth) when they correspond to stance-independent facts (independence). Barring epistemological skepticism, we may also expect suitably motivated inquirers, using proper methods of inquiry, to converge in their beliefs about this realm of objective fact since their inquiries are being constrained by an objective, stance-independent reality.

Ontological Objectivity and Moral Discourse

Does moral discourse have the trappings of ontologically objective discourse? Indeed, is it a form of **descriptive** discourse – discourse about a special subject matter, but nevertheless a discourse that is properly interpreted as representing a realm of objective moral facts? Those who think so often point to a number of 'markers' – features that are deeply embedded in moral thought and discourse – that either reflect or at least seem to support the various objectivity theses. Let us consider some of them in more detail.

Grammatical and Semantic Markers

Perhaps the most obvious markers of objectivity concern matters of grammar and semantics.

O1: Moral sentences such as 'John's lying to Brenda was wrong,' in which a moral term appears, are in the indicative mood and are used to make genuine assertions that express a (sincere) speaker's beliefs.

O2: Moreover, because moral sentences are typically used to make assertions they are truth apt: they are candidates for semantic evaluation in terms of their truth and falsity. Sentences which predicate the truth or falsity of a moral sentence seem to make perfect sense (e.g., 'It is true that John's lying to Brenda is morally wrong,' 'It is false that contraception is morally wrong,' and so on).

O3: Moreover, logically simple moral sentences (e.g., 'It is wrong to steal') can embed in all sorts of logically complex grammatical constructions, most notably truth-functional and quantificational constructions (e.g., 'If it is wrong to steal, then it is wrong to encourage others to steal.') It would seem that such logically complex sentences have truth values that are determined by the truth values of their simpler constituents.

Ontological Markers

The following two markers have to do with the ontological status of the subject matter of moral discourse.

O4: Moral terms that appear in moral sentences (e.g., 'good,' 'right,' 'virtuous,' and their opposites) seem to be used to denote properties that are (or may

be) possessed by items of moral evaluation. For example, to say of an action that it is wrong appears to attribute the property of wrongness to the action. Furthermore, some moral sentences are used with the apparent intention of picking out moral properties and talking about them, as when one utters the sentence 'It was the badness of the practice of American slavery that eventually led to its abolishment.'

O5: Moral truth and moral error are genuine possibilities. When we disagree over some moral issue, we take ourselves to be engaged in a genuine dispute where not all parties to the dispute are correct in their moral convictions. What is apparently being assumed in such disagreements is that there is a fact of the matter about the issue in dispute – that there is an objective truth about the matter. This makes it natural to think that the truth (or falsity) of a moral sentence is a matter of its correspondence (or lack of correspondence) to some moral fact. The putative fact that an action is wrong (supposing it is) would seem to be what makes true a sentence expressing this fact. Moral error results when what one says or believes fails to properly record moral reality.

Epistemological Marker

Finally, the following marker has to do with matters of justification and knowledge.

O6: We dispute moral claims by offering reasons for their truth or falsity and thus take such claims as being susceptible to justification. One can be justified or unjustified in claiming that John's action was morally wrong depending on one's evidence for the claim – evidence that can be offered, disputed, and discussed with others. Moreover, in some cases we at least suppose that we have some moral knowledge. Surely we take ourselves to know that torturing puppies for fun is morally wrong. Since justification and knowledge in ethics (as elsewhere) seems to require that there be reliable methods of inquiry suitable to the form of inquiry, one would expect there to be a moral methodology that would enable inquirers using it to reach a high level of interpersonal convergence in moral belief.

Thus, moral discourse, at least at first glance, **seems** to possess all of the characteristic marks of objectivity – indeed ontological objectivity. Many philosophers go one step further and claim that moral discourse **is** genuinely ontologically objective and that moral discourse is a kind of descriptive discourse whose primary function is to represent a realm of moral facts.

But ontological moral objectivism is controversial: we find a variety of meta-ethical positions that deny one or more of the four objectivist theses and among moral objectivists we find a variety of specific meta-ethical positions that differ over questions of semantics, metaphysics, and epistemology in relation to moral discourse. Let us now briefly survey some of these positions.

Moral Realism

One very straightforward way to accommodate O1–O6 is simply to affirm the four objectivist theses and, in particular, the idea that there is a realm of moral properties (and moral facts) that are strongly independent of our attitudes and beliefs about them and which serve as an objective basis for the truth and falsity of moral sentences. This meta-ethical position is known as moral realism and the task of this kind of realist view is to explain what sorts of fact serve as truth makers for moral judgments and how it is possible to have justified belief and perhaps knowledge of moral truths. Ontological naturalists, who are moral realists (Sturgeon, 1984; Railton, 1986, 1996; Boyd, 1988; Brink, 1989; Bloomfield, 2001), claim that moral properties and facts are identical to certain natural properties and facts – properties and facts that are the proper subject matter for empirical science to investigate. In the history of meta-ethical inquiry, we find various attempts by philosophers to 'reduce' moral properties and facts to some species of biological, psychological, or sociological fact. For instance, Spencer (1895) held that the property of being better than, which he took to be basic in ethics, could be reduced to the property of being more highly evolved. Ontological nonnaturalists in ethics (Moore, 1903; Ross, 1930; Shafer-Landau, 2003) hold that moral properties and facts are of a special nonnatural kind; that rightness, for example, is not identical to any natural property, but is nonetheless a real property.

Naturalist realists face the challenge of explaining why some specific set of natural properties and facts is identical to moral properties and facts. This in turn would seem to require a plausible semantic account of moral judgments that fits with naturalist realism, something which has proved difficult to do. Nonnaturalists, by contrast, propose to bloat our ontological commitments: in addition to being metaphysically committed to those entities in the natural world that common sense and natural science commits us to, the nonnaturalist wants to add a realm of nonnatural properties and facts. Such metaphysical

extravagance has been met with strong resistance from philosophers who think that such properties and facts are mysterious metaphysical accretions and that there are serious epistemological worries accompanying any such view.

Denying Ontological Objectivity in Moral Discourse

Some philosophers deny moral objectivism because they deny the thesis of cognitivism in relation to moral discourse. They claim that although the surface grammar strongly suggests that moral judgments express beliefs and thus are used to make truth-apt assertions, nevertheless all of this is misleading. Rather, according to the meta-ethical position known as noncognitivism (Stevenson, 1937, 1944; Ayer, 1946) and more recently as expressivism (Gibbard, 1990, 2003; Blackburn, 1993, 1998; Horgan and Timmons, 2006), moral judgments are not really in the business of expressing beliefs that purport to represent or describe moral facts; rather they instead function to express some noncognitive attitude toward the object of evaluation. Thus, for instance, according to emotivism (one kind of noncognitivism), uttering a sentence such as 'Abortion is wrong' really functions primarily to **express** one's negative feeling toward abortion and is roughly equivalent to saying, 'Abortion: boo!' So, the noncognitivist denies both the theses of cognitivism and truth (in relation to moral discourse) and hence denies the independence and convergence theses as well. What makes this view fairly radical is that it distinguishes between the surface trappings of moral discourse and its true, deep semantic working, and claims that a proper semantic interpretation of the discourse reveals that it really does not even **purport** to be objective, that, to repeat, moral sentences are not really used in thought and discourse to express beliefs capable of being true or false.

A slightly less radical view, the error theory (Mackie, 1977), maintains that although moral discourse is properly interpreted as at least purporting to be objective, its various objective pretensions result from massive error. More precisely, the error theorist accepts the thesis of cognitivism in relation to moral discourse, but denies the thesis of independence and so denies the claim that affirmative moral sentences are ever objectively true. This position is analogous to atheism. That is, an atheist holds that religious discourse involving affirmative claims about God or gods purports to be objectively true, but, claims the atheist, there are no theological facts of the relevant sort that can make true affirmative claims about God or gods, and so no such claims are objectively true. The error theorist in ethics is saying something similar. The moral judgment 'repaying one's debts is morally right' purports to attribute the property of moral rightness to the activity of repaying debts, but since there are no such moral properties this sentence and all affirmative moral sentences (taken literally) are false.

Finally, versions of moral relativism (Harman, 1984; Wong, 1984) typically affirm the theses of cognitivism and truth, but maintain that moral truth is not independent of the attitudes of individuals and groups. Rather, for a typical relativist, what makes a moral claim true is that some group accepts some set of moral principles and these principles are the very standard (for that group) that determine (together with nonmoral facts) which further moral sentences are true. The idea is that the sentences expressing moral principles are counted as true in virtue of being accepted by some group and the more specific moral sentences that (together with nonmoral facts) follow from these principles express derivative moral truths. So, if some group accepts as a basic moral principle that eating meat is morally wrong, then the sentence 'Eating meat is wrong' is true – relative to their moral outlook. If some animal (or its remains) is as a matter of fact meat, then this fact together with the general moral principle in question implies specific moral truths about eating this or that animal or its remains. Now, if some other individual or group does not have any such principle against meat eating, or has a principle that requires eating meat, then the sentence 'Eating meat is wrong' is false – relative to their outlook. Thus, for the relativist, conflicting moral sentences may be equally true.

There is a variety of ways to develop this basic relativist idea, but all of them are committed to denying the idea that there is some realm of moral fact that is independent of the stances of individuals and groups; in short, for the moral relativist, there is no single true objective morality.

Noncognitivism, the error theory, and relativism have their able defenders, but of course embracing one of these positions means having to claim either that at least some of the various objectivist markers (O1–O6) are illusory – not really characteristic of the discourse – or that they are genuine but deeply error ridden. Such views strike many philosophers as meta-ethical options we should try to avoid in making sense of moral thought and discourse (Wright, 1992; Timmons, 1999).

Methodological Objectivism

In light of the metaphysical and epistemological problems that beset realist (ontological) accounts of moral objectivity, some philosophers are attracted to

a different model of objectivity – a model that looks to the realm of mathematics and logic for a way of understanding how moral discourse can be objective even if there are no dedicated moral properties and facts (of the sort associated with ordinary descriptive discourse) that would serve as truth-makers for moral sentences. Such meta-ethical views are often called 'constructivist.' A central idea behind versions of moral constructivism, then, is that just as we need not suppose that there is a mystical realm of numbers and mathematical relations that make certain mathematical sentences true, so we need not make any heavy-duty ontological assumptions in making sense of the apparent objectivity of moral discourse (Putnam, 2004). For both sorts of discourse – mathematical and moral – so long as there are **methods** of reasoning governing these types of discourse that would lead properly motivated individuals to converge in their views on a large enough number of claims within those areas, then we have a proper basis for affirming the objective pretensions of both realms. So, in contrast to the ontological model of objectivity that emphasizes an SI thesis, the present model takes the thesis of convergence as central to moral objectivity. Let us explore this model in a bit more detail.

Suppose, then, that associated with moral discourse is a method of moral thought and reasoning that would (if properly applied) ideally lead to interpersonal convergence over a wide range of moral issues; in other words, suppose the convergence thesis holds for moral discourse. Then, according to this line of thought about objectivity, we would have the materials to vindicate the other objectivity theses – cognitivism, truth, and a modest form of independence. How might this view be developed?

The general constructivist idea is that there are better and worse methods of moral thinking – methods that involve constraints on moral deliberators and on the circumstances in which they deliberate. For instance, according to one variety of constructivism, called the 'ideal observer' theory (Firth, 1952; Carson, 1984), the proper method of moral thinking requires that moral deliberators thinking about a certain moral issue must for example have certain intellectual virtues and sufficient knowledge of non-moral facts to be in a position to arrive at moral verdicts that have the status of being true. But what is crucial to the ideal observer view and constructivist views generally is that it is the attitudes of ideal observers that constitute or make true certain moral judgments. So, although the constructivist accepts the independence thesis (in addition to cognitivism, truth, and convergence), she embraces the following modest form of this thesis in contrast to the strong form embraced by the ontological objectivist:

> Although the truth of a moral sentence is independent of the stances of actual individuals and groups, moral truth is ultimately constituted by the stances of ideal individuals or groups – call them 'ideal stances.'

Granted, some moral constructivists introduce ontological talk of moral properties and facts at this point (Rawls, 1980; Scanlon, 1998), understanding such properties and facts to be 'constructions' grounded in facts about moral convergence. But a moral constructivist need not make these ontological claims; she can rest content in emphasizing the importance of there being a method of moral inquiry that would lead all or most ideal agents (agents who are engaged in moral thinking under ideal circumstances) to converge in a great many of their moral convictions (Smith, 1994). What the constructivist hopes to do, then, is develop a meta-ethical view that satisfies the four main objectivist theses without (apparently) having to embrace heavy-duty ontological assumptions, and thereby vindicate the objectivity of moral discourse. In short: moral objectivity without (moral) ontology.

Of course, any constructivist view carries the burden of spelling out a moral methodology or process of moral reasoning that would lead ideal moral inquirers to converge in their moral views. The task of doing so poses a seeming dilemma for the moral constructivist (Timmons, 2004). On the one hand, if the favored moral methodology that is to be a basis for moral truth is characterized in morally neutral terms, then the constraints on such reasoning will be insufficient to lead those following the method to reach the level of convergence in their moral verdicts that a vindication of objectivism requires. This would mean, according to the constructivist, that there is no objective moral truth about those moral matters regarding which moral methodology fails to yield convergence under ideal conditions. Hence, the view would be committed to a kind of moral error theory – there is no fact of the matter in relation to a great many moral issues, contrary to what we suppose. On the other hand, if, in order to make the moral methodology yield substantive moral verdicts, one characterizes the methodology making use of moral assumptions, then relative to one set of moral assumptions the method will yield one set of moral 'truths,' but relative to a competing set of moral assumptions the method will yield a different and perhaps conflicting set of moral 'truths.' But this commits the constructivist to moral relativism, which, as we have seen, is at odds with the idea that moral

discourse is objective – that with respect to a large number of moral issues there is a single truth of the matter. Avoiding the error theory and relativism and thereby preserving objectivity is thus the main challenge for the moral constructivist.

Conclusion

The issue of moral objectivity, involving, as we have seen, semantic, metaphysical, and epistemological issues, is the central topic of meta-ethics. About the objectivity of moral discourse there are two questions to be distinguished. First, what sorts of objective features or markers are genuinely possessed by moral discourse? Second, assuming that moral discourse does genuinely possess such markers, how should they be interpreted? In particular, do they require, for their vindication, some version of moral objectivism? In response to these questions, we have surveyed a number of currently debated meta-ethical options, including two conceptions of objectivity.

Objects, Properties, and Functions

R J Stainton, University of Western Ontario, London, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

One of the most fundamental metaphysical distinctions is that between objects and properties. Given its depth and importance, it's perhaps unsurprising that though the distinction can be given in a canonical form, it also admits of some puzzling complexities.

By way of a first pass, let's consider some examples of objects and of properties and try to extract some hallmarks – linguistic and otherwise – of each. Examples of objects include my cat, you, the tree outside my window, and the planet Earth. These four are all physical objects. There are mental objects as well – which, depending upon whether the mental reduces to the physical, may or may not be a subvariety of physical objects. Mental objects include my wish to write a book, the pain I felt just now, my dream last night. So much for examples. Some hallmarks of objects include that they are individual things, which things (at least in the simple cases) have a specific location in space and time. What's more, objects can be counted. And, in counting, one can always ask: Is this object the same individual as that one, so that it should be counted just once, or are there two individuals here? (E.g., if Samuel Clemens is the same person as Mark Twain, then when Clemens is alone in the room, there aren't two individual people there: Clemens *and* Twain. But if Bill Clinton and Tony Blair are the sole people in the room, two people are therein.)

Examples of properties – also called 'attributes,' or "qualities" – include being red, being from Canada, being painful, knowing Charles Darwin personally, weighing exactly 16 trillion kilograms, and having belonged to Abe Lincoln. Hallmarks of properties include *not* being individual but rather being general, and being located not in one place but at various locations at once or at none. Thus the property of being from Canada is instantiated in many objects, in many places; and it might be that the property of knowing Charles Darwin personally is instantiated by no object at all these days. As for counting, while one can count *instantiations* of being red – i.e., count how many red objects there are – it doesn't really make sense to count being red itself. Another hallmark of properties, as opposed to objects, is that a given property typically has contrary or opposite properties. For instance, being green is contrary to being red, being from Spain is contrary to being from Canada, being pleasurable is contrary to being painful. (Contrast objects: What is the contrary of Abe Lincoln? What object do you get when you negate *him*? Or, again, what do you get when you negate my window? These questions don't even seem to make sense.)

There are also *linguistic* hallmarks of the object-versus-property divide. The linguistic correlates of objects are proper names ('Rob'), noun phrases ('the planet Earth'), pronouns ('me,' 'he,' 'she,' 'it'), and demonstratives (like 'this' and 'that'). The linguistic correlates of properties, by contrast, are adjectives ('red'), verb phrases ('weighs 16 trillion kilograms,' 'is from Canada') and, as above, gerundives ('belonging to me'). (In formal logic, the divide corresponds to that between constants and variables [often symbolized by lowercase letters from the beginning of the alphabet for constants, and lowercase letters from the end of the alphabet for variables: constant *a* or variable *x*] on the one hand and predicates [often symbolized by capital letters from the middle of the alphabet: F, G] on the other.) Another linguistic hallmark is this. If, following Peter Strawson (1971), we think about the different actions typically performed in speaking a sentence – for instance in saying "That cat weighs 18 pounds" – we may note that "That cat" is used for one kind of job, while "weighs 18 pounds" is used for a quite different job. "That cat" is used to *refer to*, or *talk about*, the cat. In contrast, "weighs 18 pounds" is used to *attribute* something of the cat, to *say of* it that it weighs 18 pounds. A final linguistic hallmark, then, is that in speaking, we refer to objects, but we attribute properties.

So much for the first pass at objects versus properties. The divide gets muddy, however, when we leave the canonical examples. That's because there are things that are objectlike in some respects but propertylike in others. These hard-case objects come in at least two varieties: *abstracta*, like numbers, and *kinds*, such as gold and horse. One obvious problem with such objects concerns their location. Being abstract, the square root of seven doesn't seem to have any location. The same holds for kinds: gold has multiple locations. Moreover, there are contraries to gold: silver, uranium, etc. Yet abstracta and kinds are objectlike as well. Gold *has* certain properties: it boils at 2966 °C and melts at 1063 °C. So, it isn't itself a property. And gold, along with the square root of seven, is denoted by a name; and, in speech, such things are referred to, not attributed. So, kinds and abstracta seem to exhibit some of the hallmarks of objects and some of the hallmarks of properties. At bottom, the difficulty is that such objects have instances, rather than merely being instances. To

take another case, consider the novel *War and Peace*. Some will say that it's another abstract object: it itself has no location, though its instances (i.e., copies of the book) do. But one could also take *War and Peace* to be like gold, which is located in many places at once. Whichever way one goes, it too has instances, rather than merely being an instance; and so it does not have one unique location. See Figure 1 for a summary.

One last hard case. It seems that we can form names and descriptions associated with properties. Thus, consider 'the property of being red.' This description has all the linguistic hallmarks of an object, in terms of both its form and the job it is used for. More than that, it has some of the nonlinguistic hallmarks too. We can ask whether what 'the property of being red' stands for is identical to what 'the property of being green' stands for. (Obviously the answer is no.) We can count such things. And so on. What one typically says is that 'the property of being red,' 'that property,' 'my favorite color,' and so on stand for objects that are associated with properties but do not themselves stand for properties. (Of course, this leads to the odd result that 'The property of being red is not a property' is not actually false, since according to the view under consideration, the first five words of this sentence *stand for an object*, so the sentence says of this object that it's a property – which it isn't! See Frege 1891, 1892 for a detailed discussion.)

One could continue pursuing such complexities at enormous length. For present purposes, it's enough to notice that there seem to be various kinds of objects. And several of them are propertylike in certain respects. It is in part because of the diversity of objects, and their affinities to properties, that it's hard ultimately to distinguish objects from properties.

In light of these complexities, one might wonder: Why are properties required at all? Why not just have yet another variety of object – namely, those objects that don't merely have instances (as with kinds and abstracta) but that can actually apply to other objects? Indeed, why not have the world be exhausted by its objects? Thus, on this suggestion, being from Canada would simply *be* a fourth kind of object

Figure 1 Varieties of objects.

beyond instances, kinds, and abstracta. In response, I want to give one reason that one seemingly cannot do away with the object/property distinction altogether, reducing everything to objects. It's a reason that goes back to Antiquity, and it has to do with combining in predication.

Patently, some objects can't combine predicationally at all: Rob and the tree can't be fused together into a complex fact. At best they can be combined by smashing them together or putting one inside the other or some such. But, so the 'properties are objects' idea goes, there are some objects that can combine in predication; there are certain objects that apply to others. Take Rob Stainton and being Canadian, understood, as per the proposal, as two different kinds of objects. These 'objects' combine together, in predication, in the sense that the former exhibits the latter: I am Canadian. The difficulty, however, is this: Not all objects actually so combine, even when one of them is of the supposed 'applying kind.' For instance, Rob Stainton doesn't in fact combine with being Algerian, and George Bush doesn't combine with being Canadian. So, what holds the two types of supposed objects together when the 'applying object' really does combine with the instance one? A natural thought is that the relation 'exhibiting' puts together the objects that really go together, and not the others: 'exhibiting' fuses Rob with being from Canada, but it does not fuse Rob with being from Algeria. However, if *all* things are objects, then relations – including 'exhibiting' – are objects too. And if, as we've been seeing, objects need something to put them together to distinguish those where the combination does really happen from those where it doesn't, 'exhibiting' needs something to put *it* together with – e.g., Rob and being Canadian. What, then, puts together these three objects in predication such that it doesn't fuse 'exhibiting,' Rob and being Algerian? We are faced with a choice: either there is something that is not an object and that puts objects together in predication, so that not everything is an object, or there is an infinite regress. Since the latter is absurd, we conclude that some things aren't objects. In particular, properties are non-objects, in the sense that they go together with objects in a way that two objects cannot: nothing is required to 'fuse' an object with a property. That, it is often said, is why we need some kind of object/property divide, even if it is hard to lay out.

An interesting upshot, of course, is that not all that is, is an object. Even more interesting, if anything we can refer to is an object, then if properties are not objects, we simply cannot refer to them. We can't talk about them, no matter how hard we try. At best we can refer to their associated surrogates, as in

the previous example of 'the property of being red' – which surrogates are objects, not actually properties.

Let's turn now to the relationship between properties and functions. What I hope to explain is how properties are, in a certain sense, equivalent to a peculiar kind of function: namely, a function whose output is a truth value. (See Frege 1879, 1891, 1892.) Now, mathematical functions are familiar: they take numerical inputs and yield numerical outputs. For instance, (1) is a function that takes zero as input and yields four as output, and takes one and yields nine as output, and so on.

(1) $y = (x + 2)^2$

But the notion of function can be generalized so that the inputs are not just numbers but objects of all kinds. To understand the broadening of the inputs, consider (2), which is a function that takes an individual as input and yields his or her father as output.

(2) $y =$ the father of x

If you take me as input, the output is Keith Stainton. One could also have a function whose input was a country and whose output was the language most widely spoken in that country. If Canada were taken as input, this function would output English. It should be clear that for any kind of object, we can cook up a function into which it can be input: trees, windows, universities, etc.

So, inputs to functions can be generalized. Moreover, their outputs needn't be numbers, either. Consider, in particular, a function whose output is either TRUE or FALSE (or yes/no, or 1/0, or any other pair of binary values). Specifically, consider a function that outputs TRUE if the object input meets the condition specified and that outputs FALSE if it doesn't. For instance, consider the function such that its output is TRUE if x is from Canada and its output is FALSE otherwise. This is the key point: such functions are interchangeable with the properties. To the property of being from Canada, there corresponds f, the function from objects to truth values, such that f outputs TRUE when the object is from Canada and outputs FALSE otherwise. (Gottlob Frege called such peculiar functions 'concepts'; Bertrand Russell called them propositional functions.)

We saw above that objects and properties have different linguistic correlates. Given that propositional functions are interchangeable with properties, it is unsurprising that a similar point applies to them. Specifically, the correlate of a verb phrase or an adjective will be a function from an object to a truth value. (In terms of Montague grammar, the correlate of objects will be expressions of semantic type <e>, while the correlate of (first-order) functions will be expressions of semantic type <e,t>.) And, as before, puzzles arise about whether functions are really so different from objects. At first the distinction is clear: objects are the inputs and outputs, while functions operate on them. But it seems that we can objectify functions and talk about them. This I did above: I talked about the function from things that are from Canada to TRUE. Put another way, there are functions whose inputs are functions, and functions whose outputs are functions. What's more, there are alleged objects, such as the kind gold, that seem to be true of instances; hence, they could be taken to be a propositional function, rather than as objects. But then are they just another kind of object? The answer here, again, is that there can't only be objects: we'd need something to combine 'ordinary objects' with 'function objects' that wasn't itself of either kind, or we'd have a regress. What goes for properties goes for propositional functions: there may be various kinds of objects, some of which exhibit functionlike characteristics, but we cannot do away with genuine functions altogether.

Occitan

T T Field, University of Maryland, Baltimore, MD, USA

© 2006 Elsevier Ltd. All rights reserved.

Occitan is the term used today to refer to the language that evolved out of Latin in southern France. Long called 'Provençal' and still referred to as 'la langue d'oc,' Occitan is the indigenous language of a region that covers approximately a third of France, the Aran Valley of Spain, and the upper Alpine valleys of Italy.

Status

It is difficult to speak of the sociolinguistic situation of Occitan today other than in terms of marginality. The diglossia that characterized usage among rural speakers a few decades ago, when Occitan served the domains of traditional agriculture, storytelling, and the like, has given way to what might be termed 'motivational distribution.' In other words, for most of the population, the use of Occitan is no longer clearly tied to any particular social domain, but rather is predictable only as a function of the enthusiasm of the speaker for the language and of his or her interlocutors' ability to manage in it. Outside the major cities, between 20 and 30% of the population claim to speak the language, though 40–50% say they understand it. This suggests that the number of speakers may be in the range of 2 million, with perhaps twice that number able to understand.

Occitan attained official status in the Aran Valley in 1983 and in Italy in 1999. In France, however, progress toward official recognition has been slow and uneven. Although the language has been present in the educational system on a limited basis since 1951, France as a whole remains committed to the anticommunitarian ideologies of the Third Republic and has refused to ratify the European Charter for Regional or Minority Languages.

Structure

The language to which Occitan is most closely related is Catalan, and it is increasingly common to classify both as members of an Occitano-Romance group, distinct from North Gallo-Romance and Ibero-Romance proper. As in French and Catalan, Occitan lost Latin final unstressed vowels, with the exception of -a (*filh* 'son,' *pan* 'bread,' *farina* 'flour'). Occitan phonology is distinctive historically in its failure to undergo the Romance diphthongization (*pòt* 'he can,' *pè* 'foot'); in its maintenance of /aw/ (*causa* 'thing'); and in a vowel chain shift that fronted Vulgar Latin /u/ to [y], raised /o/ and unstressed /ɔ/ to [u], and continues to raise /a/ to [o] in unstressed position (*madura* [madúro, modúro] 'ripe (f.)').

Occitan is a prodrop language and resembles Ibero-Romance in its morphology and syntax. However, it maintained, as did French, a two-case inflectional system into the 13th century. The most striking grammatical feature to be found in Occitan is the enunciative particle, which is limited to Gascon; it cooccurs with tense and serves discourse-level functions: *Joan que venó la vaca* 'John [neutral assertion] sold the cow.'

Diversity

The Occitan domains never developed institutions that promoted linguistic unity, and mutual intelligibility across regions is uneven. The major dialects are Gascon, Limousin, Auvergnat, Languedocian, and Provençal. Most linguists also identify a Vivaro-Alpine dialect. Gascon, spoken in the southwest from the Garonne to the Pyrenees, is certainly the most distinctive of these in phonology, as well as in grammar, and may well deserve separate-language status within Occitano-Romance.

Standardization has been a hotly debated issue over the past few decades. Today, most activists have adopted the orthographic norms of the Institut d'Estudis Occitans; this system ensures a level of morphophonemic abstraction sufficient to allow crossdialectal comprehension. However, the Standard Occitan proposed by the Institut has not been particularly successful. It appears today that the majority of activists are ready to see Occitan as a polycentric language, with regional norms in Gascony, Languedoc, Limousin, Provence, etc.

History

The earliest extensive Occitan texts date from the 11th century. The 12th century marks the opening of the language's classical period, when the troubadours (an Occitan word) produced their stunningly innovative poetic tradition and launched a genre dialect that would remain an international model of poetic creativity for nearly two centuries. However, as most of the Occitan regions were integrated into the kingdom of France, the language lost ground to French. In Bearn and Lower Navarre, it retained official status through the 18th century. By 1900, French had established its 'high' status in a diglossic situation that continued to evolve to its advantage. Although there were still a few children reared as monolinguals in Occitan in the early 1950s, the language had nearly disappeared from the cities and larger towns and was

almost universally associated with backwardness and ignorance.

Two major movements have had the goal of revitalizing Occitan. The first of these was the 'Felibrige,' founded in 1854 and centered on the personality of Frederic Mistral. This movement had an enduring influence in Provence, and it may well account for the vitality of Provençal in the face of a very heavy influx of outsiders. The second movement, 'Occitanism,' aimed to unify the language and open up modern spaces for Occitan use. In the 1970s, this movement was responsible for a surge of public visibility for the language and for a dramatic increase in its range of uses (e.g., theater, popular song, and academic writing). Occitanism also engendered the *Calandretas*, which are bilingual private schools in which Occitan once again plays a role in children's education and socialization.

Perspectives

Despite the progress made by activists in the final decades of the 20th century, and despite favorable official policy in small areas of Spain and Italy, Occitan continues to decline, and, as time passes, speakers who acquired the language in family and community settings are disappearing rapidly. The children who emerge as fluent speakers from the *Calandretas* and the enthusiasts who manage to pick up Occitan as a second language rarely have access to community settings in which speaking can take root. There can be no doubt that Occitanism has prolonged the life of the language and that there will continue to be people who speak, read, and write Occitan for many decades to come, but the time is near when speakers who learned the language in traditional communities will no longer exist.

Ogam

J M Y Simpson, University of Aberdeen, Aberdeen, UK

© 2006 Elsevier Ltd. All rights reserved.

Ogam, or ogham, is an alphabetic system originally realized in notches cut on stone slabs and almost exclusively used for writing Old Irish. (The spelling *ogam* is that of Old Irish; *ogham* is a version reflecting the pronunciation /o:m/; both are in scholarly use.)

Epigraphic Ogam

Some 300 Old Irish lapidary inscriptions in ogam are to be found in Ireland (for the most part in the southwest, principally in Kerry), but an additional 57 are outside Ireland, 40 being in Wales (Price, 2000a: 38) and the remainder in England, the Isle of Man, and Scotland. The Irish inscriptions have been dated to between the 4th and 6th centuries C.E. and the Welsh to a slightly later period. The existence of such inscriptions outside Ireland makes it possible to argue for the continuing presence of Irish-speaking colonies in western southern Britain until the 6th or even the 7th centuries (Jackson, 1953: 171).

These inscriptions are in general very short, being funerary formulae marking a grave or memorial. Each is usually a stock phrase consisting of a personal name followed by 'son of' and a patronymic, all three nouns being in the genitive. They are therefore of limited, though not discountable, philological value to historians of the Irish language.

The system was highly wasteful of space, being realized in irregularly shaped dots or the lines drawn on or across one edge, or *arris*, of a slab or to one or other side of it. Twenty letters could be encoded in this way; they were divided into four groups, each containing from one to five identical notches (see **Figure 1**). Typically a lapidary inscription would begin at the bottom of the left edge, continue up over the top, and then terminate down the right edge. There were no word divisions or punctuation.

It is usual to transliterate these symbols by uppercase letters. ⟨C⟩ = [κ]; for further discussion see McManus, 1991. Sims-Williams (1993) argues convincingly that the letters traditionally transcribed

almost universally associated with backwardness and ignorance.

Epigraphic Ogam

Some 300 Old Irish lapidary inscriptions in ogam are to be found in Ireland (for the most part in the southwest, principally in Kerry), but an additional 57 are outside Ireland, 40 being in Wales (Price, 2000a: 38) and the remainder in England, the Isle of Man, and Scotland. The Irish inscriptions have been dated to between the 4th and 6th centuries C.E. and the Welsh to a slightly later period. The existence of such inscriptions outside Ireland makes it possible to argue for the continuing presence of Irish-speaking colonies in western southern Britain until the 6th or even the 7th centuries (Jackson, 1953: 171).

These inscriptions are in general very short, being funerary formulae marking a grave or memorial. Each is usually a stock phrase consisting of a personal name followed by 'son of' and a patronymic, all three nouns being in the genitive. They are therefore of limited, though not discountable, philological value to historians of the Irish language.

The system was highly wasteful of space, being realized in irregularly shaped dots or the lines drawn on or across one edge, or *arris*, of a slab or to one or other side of it. Twenty letters could be encoded in this way; they were divided into four groups, each containing from one to five identical notches (see **Figure 1**). Typically a lapidary inscription would begin at the bottom of the left edge, continue up over the top, and then terminate down the right edge. There were no word divisions or punctuation.

It is usual to transliterate these symbols by uppercase letters. ⟨C⟩ = [κ]; for further discussion see McManus, 1991. Sims-Williams (1993) argues convincingly that the letters traditionally transcribed

Figure 1 The Ogam alphabet.

as ⟨Z⟩ and ⟨NG⟩ represent respectively [sw] (or perhaps some other reflex of P. I.-E. [st]) and [g^w].

Scholastic Ogam

After the period of epigraphic inscriptions, ogam appeared in manuscripts ('scholastic ogam'). In these, the symbols were written horizontally from right to left, sometimes with word divisions indicated. A treatise on ogam, in the 10th- or 11th-century C.E. *Auraicept na n-Éces* ('The Scholars' Primer'), copied into the 14th- or 15th-century C.E. 'Book of Ballymote' and other extant sources, gives the list of ogam characters with their names.

Each ogam letter was called by an acrophonic name of a tree and a bird. Thus (Calder, 1917; Marstrander *et al.*, 1917–1976): ⟨B⟩ *beithe* 'birch', *besan* 'pheasant'; ⟨L⟩ *luis* 'rowan', *lacha* 'duck'; ⟨N⟩ *nion* 'ash', *naoscach* 'snipe'; ⟨F⟩ *fearn* 'alder', *faoileán* 'gull'; ⟨S⟩ *saileach* 'willow', *seabhac* 'hawk'; ⟨H⟩ *(h)uath* 'hawthorn', *(h)adaig* 'night crow'; ⟨D⟩ *dair* 'oak', *dreoilin* 'wren'; ⟨T⟩ *tinne* 'holly', *truit* 'starling'; ⟨C⟩ *coll* hazel', *corr* 'crane'; ⟨M⟩ *muin* 'vine', *meantán* 'titmouse; ⟨G⟩ *gort* 'ivy', *géis* 'mute swan'; ⟨NG⟩ *(n)getal* 'broom', *(n)gé* 'goose'; ⟨R⟩ *ruis* 'elder', *rocnat* 'rook'; ⟨A⟩ *ailme* 'pine', *airhircleog* 'lapwing'; ⟨O⟩ *onn* 'furze', *odoroscrach* 'cormorant'; ⟨U⟩ *úr* 'heather', *uiseóg 'skylark*'; ⟨E⟩ *edad* 'poplar', *ela* 'whistling swan'; ⟨I⟩ *iúr* 'yew', *illait* 'eaglet'.

The ogam alphabet is consequently sometimes known as the *Beithe-Luis* or *Beithe-Luis-Nion* (or *–Nin*) after the first letters. Ogam had fallen out of use by the end of the medieval period.

Pictish Ogam

Ogam is also used in almost three dozen other inscriptions that are manifestly not in Old Irish. These are all in Scotland, indeed within the Pictish area, and have been dated from the 7th to the 10th centuries C.E. (In them the baseline was sometimes drawn across the face of the slab.) From their location and presumed date it would be reasonable to conclude that the language written is Pictish. Unfortunately, assuming that the values assigned to Irish ogam apply also to these inscriptions, the readings are bizarre in the extreme, and none of them is immediately intelligible, a typical example being ETTYCUHETTS AHEHHTANNN HCCVVEVV NEHHTONN. This fact has resulted over the years in a number of imaginative proposals, ranging from claims that the language written is not Indo-European, or even that it is Basque, to a conjecture that the inscriptions are complete nonsense, being the work of a mason intent on deceiving a gullible, illiterate patron (see for example Rhŷs, 1892–1893; Macalister, 1940; Jackson, 1956; Price, 1984). A painstaking investigation (Cox, 1999) claims that the language recorded is not Pictish but Old Norse. However, Ó Dochartaigh (1999) persuasively demonstrates that the methodology involved is seriously flawed and that what Cox has proved is that the language is **not** Old Norse. Forsyth (1995 and 1997) cogently argues that there is no reason for supposing that the language is anything but Celtic and that at least one inscription previously thought to be impenetrable can be interpreted. One can conclude that more work remains to be done in identifying the symbols where weathering allows, reading them in the correct order, assigning word spaces, and, if possible, deciding what sort of a text is written. An indispensable clearing of the ground for this is Forsyth (1996).

Figure 2 Additional, or *Forfeda*, letters.

Additional Letters

An additional set of letters, known as *forfeda*, of very different aspect, is attested in manuscripts and only on later stones, including the Pictish (see Sims-Williams, 1992). They are shown in Figure 2. They represent sounds that had appeared as a result of historical developments in Irish, and it has been conjectured that some at least are based on Greek shapes (see Lehmann, 1989).

The Origin of Ogam

According to the *Auraicept*, the system is named after its inventor, Ogma. (He was the son of the God of

Eloquence or Culture, whose name appears in Gaul as Ogmios and whose tasks included that of taking souls to the Other World.) Scholarly investigation does not yield anything more in the way of hard evidence, and various mutually exclusive conjectures have been made about the origin of ogam. It has been contended that ogam was influenced by runes, that runes were influenced by ogam, that each influenced the other, that the origin was in wooden tally sticks used for counting, that ogam developed from finger signaling, and that ogam originated in Phoenician. (See Vendryès, 1948; Lehmann, 1989; and Russell, 1995.)

It is tempting to regard ogam as a direct encoding of the Latin alphabet, especially as Old Irish would require seven long vowel phonemes but ogam offers only five, as in Latin. However, ogam distinguishes between /u/ represented by ⟨U⟩ and /w/ represented by ⟨F/V⟩ although both /u/ and /w/ were represented in the Latin by ⟨V⟩. It has therefore been suggested that the vowels were first notated by dots (for which there is a Latin precedent) and then this technique was extended to symbols necessary to notate the consonants of Irish (Sims-Williams, 1993). Perhaps supporting a Latin origin, Henken (1942) reports a find of bone dice dating perhaps to the 2nd century C.E. that may show a knowledge of both Roman numerals and ogam.

Ogam in Divination, Magic, and Myth

The medieval manuscripts (for example, see Calder, 1917: 278 ff.) give not only the names of the symbols but some kind of divinatory connotation of each, singly or in combination with others. This, together with the supposed divine origin of the script, has in some quarters given rise to a mystical view of ogam in which it is combined with such things as Celtic legend, religion, magic, the activities of druids, and the mythical import of writing generally (see, for example, Graves, 1961; and Thorsson, 1992).

Ogden, Charles Kay (1889–1957)

P P Chruszczewski, University of Wrocław, Wrołcaw, Poland

© 2006 Elsevier Ltd. All rights reserved.

Charles Kay Ogden (C. K. Ogden) (1889–1957) (known also under the pseudonyms of Adelyne More, Dorothy Gates, T. L., and C. M.) was born on June 1, 1889 to Charles Burdett Ogden and his wife Fanny Hart at Rossall School in Fleetwood, England. C. K. Ogden was good at sports (soccer, chess) until at the age of 16, rheumatic fever kept him in bed for approximately 2 years, but even after that traumatic experience he represented Cambridge University against Oxford at billiards in 1909. Ogden went to Cambridge in 1908 having been awarded a classical scholarship, and made the influence of the Greek language on Greek thought his main field of specialization. Ogden was a founding member of the *Heretics* (he first served as secretary, then for 12 years as president), a society established in order to freely discuss religion, philosophy, and art (honorary members included Bertrand Russell, George Bernard Shaw, and G. M. Trevelyan). From 1912 to 1922, Ogden was founder and editor of the *Cambridge Magazine* where readers were introduced to the issues of philosophy, psychology, aesthetics, and religion as well as language philosophy; from 1923 to 1952 he also edited *Psyche*, a journal of general and linguistic psychology. Ogden spent considerable time studying translation methods. He translated from French and German. He translated, among others, Wittgenstein's *Tractatus Logico-Philosophicus*. Together with I. A. Richards, Ogden worked on the project published under the title *The meaning of meaning: a study of the influence of language upon thought and of the science of symbolism* (London, 1923). Ogden was of the opinion that language (and via language also men) can be controlled, which could be turned to the benefit of effective communication and international understanding. In 1912–1913, Ogden visited schools and universities in Europe and the United States studying language teaching methods. He is believed to be the father of *Basic English* – a new artificial language – that was supposed to become a new lingua franca. Bearing in mind the process of globalization in education and 'shrinking distances' due to mass media proliferation, he proposed a program emphasizing reductive principles: 1) reducing the number of Basic English words for specialized subjects; 2) creating a Basic Library of General Knowledge covering the sciences in 1000 divisions; 3) establishing a Basic Parallel Library of 1000 books that would be composed of the basic form of the works of great writers. He reduced the English verb stock to 18 and came up with the idea of a word system with approximately 850 words, in which – for the sake of simplicity and clarity – words would be used only in their fundamental meanings. He divided the words into three groups (600 nouns; 78 pronouns, adverbs, and prepositions; 150 adjectives). The nouns and adjectives were divided into two groups: general and picturable. Grammatical rules were reduced to seven. By 1935, Basic English teaching centers and their representatives were to be found in 30 countries. There were also programs regularly broadcast in Basic English in many countries (including North America, South America, Africa, India, and China). The British Prime Minister Winston Churchill applauded Basic English in his Harvard speech in 1943, stating that he and President Roosevelt were of the opinion that it had "high merit as a possible international auxiliary language."

Ohno, Susumu (b. 1919)

N Harada, Media Information Science Laboratories, Kyoto, Japan

© 2006 Elsevier Ltd. All rights reserved.

Ohno, Professor Emeritus of the Gakushuin University (Tokyo, Japan), has been actively engaged in research projects as well as projects outside academia, and is considered as one of the most renowned traditional Japanese grammarians. Born in 1919 in the center of Tokyo in a family of merchants, Ohno noted a difference between the cultures of downtown and uptown Tokyo, which made him ponder the fundamental elements of the Japanese culture. This contemplation on the culture of Japan led him to major in Japanese grammar at the University of Tokyo (then called the Imperial University of Tokyo), where he studied under Shinkichi Hashimoto (1887–1945) until 1943. Influenced by Hashimoto, Ohno engaged in the study of *zyoodai tokusyu kanadukai* (phonetically based Chinese characters) and reconsidered the phonemic system of Old Japanese in the Nara period (710–794). Ohno is known for his philological work on publications by Norinaga Motoori (1730–1801), a Japanese grammarian investigating agreement/concord relations between particles and verbal endings. Ohno's interest in Norinaga Motoori's work led him to the survey of *kakarimusubi* (the concord phenomena in Old-Middle Japanese). Ohno is also engaged in editing a dictionary of Old-Middle Japanese: *Iwanami kogo ziten* (first edition published in 1974), which has successfully gone through several printings and is regarded as one of the most popular dictionaries on Old-Middle Japanese.

In addition to the works on Old-Middle Japanese, Ohno has been ardently pursuing the genealogy of Japanese. After conducting a comparative study of Korean, Ainu, and several other languages (see Ohno, 1957), Ohno gradually took an interest in the Dravidian languages, among which he focused on Tamil (with emphasis on classical Tamil). In collaboration with Arunasalam Sanmugadas from the University of Jaffna in Sri Lanka and Manonmani Sanmugadas (wife of Arunasalam), Ohno conducted an extensive comparative study of Old Japanese and Old Tamil with regard to the lexicon, morphology, syntax, and prosody, after which he reached the conclusion that Japanese is genetically related to Tamil. Ohno's hypothesis can be regarded as the most radical variant of the southern substratum theory of the origin of Japanese, which claims that Japanese has an Austronesian lexical substratum. This highly controversial hypothesis on the origin of Japanese has come to be well-known to both academic and nonacademic audiences.

Aside from academic works, Ohno enthusiastically publishes books for enlightening general readers, whose topics vary from novel interpretations of *Genji monogatari* (*The Tale of Genji*), the genetic affiliation of Japanese, interactions between the language and the culture of Japan, the grammar of Japanese, among others. His recent book for general readers titled *Nihongo rensyuutyoo* (A workbook for practicing Japanese) has sold nearly two million copies since its publication in 1999.

Okamoto, Shigeko

M Makihara, Queen's College, Flushing, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Shigeko Okamoto studied English literature at Kyoto Prefectural University in Japan, and moved to the United States for her graduate studies in linguistics. She obtained her M.A. from California State University, Fresno, and her Ph.D. from the University of California, Berkeley in 1985. Her dissertation was on ellipsis in Japanese discourse. In 1986, she joined the Department of Linguistics at California State University, Fresno, where she continues to teach as professor of linguistics and Japanese.

She has published extensively on the Japanese language in the areas of pragmatics, semantics, discourse analysis, sociolinguistics, language and gender, language and culture, and language pedagogy. Some of her contributions are the result of her collaboration with other linguists such as Janet Shibamoto Smith, Shie Sato, Meryl Siegal, Yoshiko Matsumoto, and Haruo Aoki. Her earlier works focused on the examination of the relationship between syntax, semantics and pragmatics in Japanese discourse. In her analysis of nominal tautological constructions (e.g., *boys are boys*), for example, she extended the research to their use in discourse and to non-European language, and critically examined the adequacy of pragmatic and semantic approaches offered by the works of Paul H. Grice and Anna Wierzbicka in interpreting the discourse context dependency in the functions of the Japanese morphosyntactic patterns found in these constructions (Okamoto, 1993). Much of her recent research concerns topics in the area of sociolinguistics, including honorifics, gendered speech, regional dialects, and Japanese interaction styles (e.g. Okamoto, 1999). She has also published papers in the area of teaching Japanese as a foreign language (e.g., Matsumoto and Okamoto, 2003).

Through her approach to linguistic meaning, which emphasizes the analysis of language use, she has made significant contributions to the study of Japanese language and gender. In a series of papers (e.g., Okamoto, 1995; Okamoto and Sato, 1992), she documents diverse patterns in the use of feminine speech styles, for example, the way that young Japanese women use less feminine speech and even masculine sentence final particles in natural conversations. Her work thus gives special attention to the relationship between Japanese linguistic features and social and communicative contexts, in particular gender identity and social distance and hierarchy among participants. For example, in her works on honorifics and sentence-final particles, she examined the wide variation in the use of these indexicals, and the interactional and sociocultural factors influencing speakers' choice of speech styles (e.g., Okamoto, 1997). Most recently, she co-edited with Janet S. Shibamoto Smith *Japanese language, gender, and ideology: cultural models and real people* (2004).

Old Church Slavonic

C M MacRobert, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Old Church Slavonic is the earliest Slavic literary language. It was first used in the later part of the 9th century A.D. as the vehicle of translations and original compositions by SS Cyril and Methodius and their associates for the benefit of those Slav peoples who had recently accepted Christianity. Some of these texts have survived in copies thought to date from the late 10th or 11th century, which are the primary source of information about the language and have recently been supplemented by newly discovered manuscripts; others, found in copies of later date, can be used to provide important additional evidence about syntax and lexis.

The sound system implied by the two alphabets Glagolitic and Cyrillic, in which Old Church Slavonic was written, antedates the major change from open to closed syllable structure that took place across the Slavic languages between the 10th and 12th centuries. Some of the grammatical forms and constructions used in Old Church Slavonic manuscripts are also highly conservative, e.g., substantial remains of distinct consonantal nominal declensions, transparent postposition of the anaphoric pronoun to adjectival forms as a means of expressing definiteness, asigmatic aorist forms, and the supine with a genitive complement. The evidence of Old Church Slavonic therefore has considerable weight in attempts to reconstruct Proto-Slavic (Common Slavonic) and to elucidate the relationship between Slavic and other Indo-European languages (*see* **Indo–European Languages**).

Old Church Slavonic is also the main source of information about the early history of the South-East Slavic languages (*see* **Bulgarian, Macedonia: Language Situation**). As natives of Saloniki, SS Cyril and Methodius doubtless spoke the local variety of South Slavic. As a result of their work in Moravia (863–885 A.D.), Old Church Slavonic borrowed some local items of religious terminology from Latin or Old High German, such as *mĭša* < *missa*, *vŭsodŭ* < *wizzǫd*, and there is some ground for supposing that at an early stage, Old Church Slavonic also incorporated certain West Slavic linguistic features, particularly in pronunciation. However, the manuscripts of South Slavic origin, from which the information about Old Church Slavonic is largely derived, preserve only traces of such a hybrid usage at best, and for the most part reflect the Slavic dialects of the southeast Balkans and the Greek terminology of the Eastern Orthodox Church.

From its inception, however, Old Church Slavonic must have differed from contemporary spoken varieties of Slavic, as it was used primarily to translate Scriptural, liturgical, and patristic texts from Greek or occasionally from Latin and Old High German. Even pronunciation may have been modified to accommodate Greek loanwords: the Glagolitic alphabet has extra letters for the velar consonants /g/ and /x/, which seem to have been reserved for use in Greek loanwords before front vowels, a position in which these phonemes did not occur in native Slavic words at that time. Comparison with the originals shows that the translations aimed at faithfulness on the basis of correspondence, phrase by phrase, between source and target. Consequently, while the grammatical forms and most of the words and semantic distinctions are Slavic, the syntax tends to mirror the constructions of the original, usually Greek.

There is, however, a range of recurrent exceptions where imitation of a foreign model would presumably have led to linguistically unacceptable results: the placing of clitics apparently follows Slavic rules; possessive adjectives or the attributive dative frequently appear in place of an attributive genitive in the original, and simple case forms may be used to translate prepositional phrases; the use of the dual number, the distribution of subordinate complementary clause, infinitive and supine, and the choices made among the elaborate past tense system of the verb are all independent of Greek. Even the dative absolute construction, which is peculiar to Old Church Slavonic among the Slavic languages and is usually found as a translation equivalent of the Greek genitive absolute, is occasionally used to render intractable Greek constructions such as the nominalized infinitive. The compound word-formations of Greek were also frequently reproduced in Old Church Slavonic, e.g., *pravoslovie* (later *pravoslavie*) < ορθοδοξία. Texts believed to be original Old Church Slavonic compositions display the same type of language, which can be characterized as a compromise between early Slavic idiom and Greek literary usage in a balance so delicate that it was not subsequently maintained (*see* **Church Slavonic**).

Old English Dictionaries

D A Bankert, James Madison University, Harrisonburg, VA, USA

© 2006 Elsevier Ltd. All rights reserved.

The first published Old English dictionary was William Somner's *Dictionarium Saxonico-Latino-Anglicum* (1659). It was built on his predecessors' unpublished Old English dictionaries and glossaries, beginning with Laurence Nowell's 'Vocabularium Saxonicum,' compiled in the mid-15th century with the assistance of William Lambard, whose own *Archaionomia* (*ca.* 1568) included a list of Old English legal terms. John Joscelyn, Archbishop Matthew Parker's Latin Secretary, began compiling his 'Dictionarium Saxonico-Latinum' around 1566. Much longer than Nowell's and unfinished at the author's death in 1603, the manuscript was bequeathed to Sir Robert Cotton, who made it available to the next generation of Old English lexicographers.

During the 17th century, a number of important Old English dictionaries, word lists, and glossaries were prepared from extant Anglo-Saxon manuscripts. The most important of the compilers were Sir Henry Spelman, who published half of his projected two-volume glossary of Old English legal terms, *Archaeologus in modum glossarii ad rem antiquam posteriorum*, in 1626; Abraham Wheelock ('Lexicon Saxonicum-Latinum,' compiled *ca.* 1639); and William Dugdale, whose 'Dictionarium Saxonicum' is notable for its emphasis on variants. Others on whom Somner drew include Jan de Laet, Friedrich Lindenbrog, Richard Roland Verstegan, John Selden, William Lisle (Spelman's son-in-law), Sir William Boswell, Francis Tate, Richard James (Robert Cotton's librarian), as well as Simonds D'Ewes, the first to draw chiefly from his predecessors rather than from the original manuscripts.

The 18th century produced one important published contender to Somner's *Dictionarium*, Edward Lye's *Dictionarium Saxonico et Gothico-Latinum*, edited and published in 1772 by Owen Manning after Lye's death. The work of Somner and Lye together served Anglo-Saxon scholars until 1838, when Joseph Bosworth, at the time a British chaplain in the Netherlands, published *A Dictionary of the Anglo-Saxon language*, the first truly comprehensive Old English dictionary. Despite mixed reviews, it and his abridged *A compendious Anglo-Saxon and English dictionary* (1848) quickly replaced Somner and Lye as the standard Old English dictionary. Bosworth's work on a revised and enlarged edition was never completed. Two years after his death, in 1878, Oxford University Press, now owner of the copyright, turned the project over to Thomas Northcote Toller, a young lecturer at Owens College (later University of Manchester). Toller spent the next 35 years editing and enlarging Bosworth's dictionary, serially publishing *An Anglo-Saxon dictionary based on the manuscript collections of the late Joseph Bosworth* between 1882 and 1898, and a lengthy *Supplement*, also serially, between 1908 and 1921.

Also published in the late 19th century were two important dictionaries aimed chiefly at students: J. R. Clark Hall, *A concise Anglo-Saxon dictionary* (1894) and Henry Sweet, *The student's dictionary of Anglo-Saxon* (1896). In 1972, Alistair Campell published *The enlarged addenda and corrigenda* to Bosworth-Toller,

Also published in the late 19th century were two important dictionaries aimed chiefly at students: J. R. Clark Hall, *A concise Anglo-Saxon dictionary* (1894) and Henry Sweet, *The student's dictionary of Anglo-Saxon* (1896). In 1972, Alistair Campell published *The enlarged addenda and corrigenda* to Bosworth-Toller,

as it had come to be called, the final addition to this seminal work.

In 1969 and 1970, two conferences were held at the University of Toronto; their purpose was to design a scholarly dictionary to replace Bosworth-Toller that would take advantage of new computer technologies and increases in manuscript editing (see Cameron *et al.*, 1970 and Frank and Cameron, 1973 for proceedings). The result was the *Dictionary of Old English*, which is still in progress. Originally published in microfiche, the first electronic version, *Dictionary of Old English: A to F on CD-ROM*, was published in 2003. At the date of this writing, entries for the letters G, H, I, and Y are being written with G shortly due out on microfiche.

Old French Dictionaries

D A Trotter, University of Wales Aberystwyth, Aberystwyth, Wales, UK

© 2006 Elsevier Ltd. All rights reserved.

There are six Old French dictionaries of scientific importance:

1. Godefroy, *Dictionnaire de l'ancienne langue française* (Gdf);
2. Tobler/Lommatzsch, *Altfranzösisches Wörterbuch* (TL);
3. *Dictionnaire étymologique de l'ancien français* (DEAF);
4. *Anglo-Norman dictionary* (AND);
5. *Dictionnaire du moyen français* (DMF);
6. *Französisches Etymologisches Wörterbuch* (FEW).

Gdf is the earliest and the most comprehensive: it covers the whole medieval period (and trespasses on the 16th century and beyond). Initially, Gdf did not include any word still current in French, which means that significant amounts of the lexis of Old French (which has survived intact into modern French) was omitted. The *Complément* (in vols. 8–10) remedies this. Gdf is more comprehensive than rigorous: it tends to accumulate examples, and the glossing is often imprecise. A CD-ROM version of Gdf exists, but it is unreliable. TL, originally conceived as a supplement to Gdf, is more philologically precise, but limited both in time (pre–1350) and register (overwhelmingly literary). A CD-ROM version, with image files (JPEG) accessible from a rekeyed lemma list, is now available. A weakness of TL is its tendency (like Gdf) to list a run of quotations without differentiating the gloss, and to use (as does Gdf) often heavily normalized headword forms, some of which are unattested anywhere. DEAF is as yet incomplete and will be for some time (G, H, I and part of J are in print at the time of writing, together with indexes to the completed letters). It is both a

DEAF is as yet incomplete and will be for some time (G, H, I and part of J are in print at the time of writing, together with indexes to the completed letters). It is both a

remarkable dictionary of Old French, drawing with exemplary precision on an unparalleled range of documents, and a rewriting (for Old French) of the FEW. When complete, it will be the nearest thing to a definitive Old French dictionary. AND theoretically covers only Anglo-Norman (from 1066 until *ca.* 1450), but because that variety is in large part (lexically) simply French, in practice it is also a dictionary of Old French; a second edition is in press (A–E) and is also available online in a fully searchable format. DMF has had difficulty being published (even though it is an essential element in the lexicography of French, covering as it does the gap between TL and the 16th century); it is currently being made available online in instalments of its base lexica. FEW, an etymological dictionary of French (25 volumes to date), is an invaluable source of information on Old French, particularly in the more recent parts of the dictionary (except for the revised A, coverage is poor in the first half of the alphabet).

Oldendorp, Christian Georg Andreas (1721–1787)

K W Lindley, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

Born on March 8, 1721 in Grossenlafferte near Hildesheim in Lower Saxony, Christian George Andreas Oldendorp was orphaned at an early age. His eldest brother, Johann Christoph Oldendorp, a pastor in Grossenlafferte, undertook his upbringing, and from 1731 he attended the gymnasium in Hildesheim, demonstrating a propensity for religious studies and an intellectual interest in a wide variety of other subjects, including botany. As a student of theology at the University of Jena in 1740, he was strongly influenced by another brother, Joann Siegfried, also a student at the university, who introduced his younger sibling to the Moravian Brethren. In 1743, the Brethren gave Christian a position as a teacher of children, a profession he intermittently pursued until his death. After the age of 26, Christian Oldendorp led a peripatetic lifestyle, residing first in Hernnhut, the center of the Moravian Brethren, and also serving as a teacher at Trebka in Silesia, Niesky, Hennersdorf, and Marienborn. In February of 1766, at the age of 44, he was engaged by the Brethren to write a history of the missions in the Danish West Indies, and so, in September of that year, set out from Niesky for the islands. An arduous 6-month sea journey brought him to St. Croix, where he immediately began an exhaustive study of not only the missions, but also of the flora, fauna, and inhabitants of the various islands. In all, Oldendorp spent 17 months in the Danish West Indies satisfying his voracious curiosity by making observations of his natural surroundings, researching historical documents, and interviewing members of all the social classes resident in the islands, including, and perhaps most significantly, slaves. Returning to Europe via the Moravian mission in Bethlehem, Pennsylvania, where he spent the winter of 1768–1769, Oldendorp was back in Marienborn by June 1769. There he began the task of converting his copious notes into an excellent two-volume description of the Danish West Indies, but the 3272-page manuscript he eventually produced underwent heavy editing by Johan Jakob Bossard before final publication in a much-reduced form in 1777. It is the original version of the manuscript that contains the fine 53-page description of Negerhollands, the Dutch-based creole of the Danish West Indies, which secures for Oldendorp a place as one of the founding fathers of Creolistics. The considerable insight he

Oldendorp, Christian Georg Andreas (1721–1787)

K W Lindley, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

Born on March 8, 1721 in Grossenlafferte near Hildesheim in Lower Saxony, Christian George Andreas Oldendorp was orphaned at an early age. His eldest brother, Johann Christoph Oldendorp, a pastor in Grossenlafferte, undertook his upbringing, and from 1731 he attended the gymnasium in Hildesheim, demonstrating a propensity for religious studies and an intellectual interest in a wide variety of other subjects, including botany. As a student of theology at the University of Jena in 1740, he was strongly influenced by another brother, Joann Siegfried, also a student at the university, who introduced his younger sibling to the Moravian Brethren. In 1743, the Brethren gave Christian a position as a teacher of children, a profession he intermittently pursued until his death. After the age of 26, Christian Oldendorp led a peripatetic lifestyle, residing first in Hernnhut, the center of the Moravian Brethren, and also serving as a teacher at Trebka in Silesia, Niesky, Hennersdorf, and Marienborn. In February of 1766, at the age of 44, he was engaged by the Brethren to write a history of the missions in the Danish West Indies, and so, in September of that year, set out from Niesky for the islands. An arduous 6-month sea journey brought him to St. Croix, where he immediately began an exhaustive study of not only the missions, but also of the flora, fauna, and inhabitants of the various islands. In all, Oldendorp spent 17 months in the Danish West Indies satisfying his voracious curiosity by making observations of his natural surroundings, researching historical documents, and interviewing members of all the social classes resident in the islands, including, and perhaps most significantly, slaves. Returning to Europe via the Moravian mission in Bethlehem, Pennsylvania, where he spent the winter of 1768–1769, Oldendorp was back in Marienborn by June 1769. There he began the task of converting his copious notes into an excellent two-volume description of the Danish West Indies, but the 3272-page manuscript he eventually produced underwent heavy editing by Johan Jakob Bossard before final publication in a much-reduced form in 1777. It is the original version of the manuscript that contains the fine 53-page description of Negerhollands, the Dutch-based creole of the Danish West Indies, which secures for Oldendorp a place as one of the founding fathers of Creolistics. The considerable insight he

gained from his time spent talking with the islands' blacks, both natives and African-born, allowed him to compile extensive notes on their lingua franca, Negerhollands. Although only four pages eventually appeared in the inferior published version, the importance to Creolistics of Oldendorp's thorough description of the language's grammar and usage in social contexts is difficult to overstate. Along with his later German-Negerhollands dictionary (*Criolisches Wörterbuch. erster zu vermehrender, und, wo nötig, zu verbessernder Versuch*), it may be considered a standard for subsequent similar works in the field. Christian George Andreas Oldendorp died of dropsy in Ebersdorf at the age of 67 on March 9, 1787.

Speakers and Linguistic Resources

Omaha-Ponca is the name linguists use for the language of the Omaha and Ponca peoples. *Umo^{n}ho^n* (Omaha) and *Pa^{n}ka* (Ponca, sometimes spelled Ponka) dialects differ only minimally, but are considered distinct languages by their speakers. Both tribes formerly inhabited areas near the Missouri River in northeastern Nebraska. The Omahas are still located in this area, with the tribal headquarters at Macy, Nebraska, but most of the Poncas were removed in 1878 to northern Oklahoma, around Ponca City. A smaller group of Poncas still resides in Nebraska. The Omaha-Ponca language is a member of the Dhegiha branch of Mississippi Valley Siouan, closely related to the Osage, Kansa, and Quapaw languages (for more detail on the genetic relationships of the Siouan languages, *see* **Siouan Languages**).

The Omaha and Ponca dialects are severely endangered, with only a few dozen elderly fluent speakers of Omaha in Nebraska and of Ponca in Oklahoma. However, many younger people have some ability to speak or understand the languages, and language classes at several schools and colleges in Nebraska and Oklahoma have had some success in promoting fluency among passive speakers and semispeakers, as well as in teaching the language to children and college students. Major linguistic resources on Omaha-Ponca include the monumental text collections of James Owen Dorsey (1890, 1891) and Dorsey's draft grammar and slip file, the ethnographic studies by Fletcher and LaFlesche (1911) and Howard (1965), Swetland's dictionary (1991), and an unpublished grammar by Koontz (1984). Several dissertations are currently in progress.

Sounds and Spelling

Traditionally, like other Native American languages, Omaha-Ponca was not written. Independently, both tribes recently adopted nearly identical spelling systems, similar to the orthography used by Fletcher and LaFlesche, but reading and writing Omaha-Ponca are still complicated by the existence of several other orthographies. In particular, the Dorsey materials, the largest source of texts in the language, are written in an idiosyncratic orthography that uses upside-down letters for unaspirated stops, '¢' for the dental

gained from his time spent talking with the islands' blacks, both natives and African-born, allowed him to compile extensive notes on their lingua franca, Negerhollands. Although only four pages eventually appeared in the inferior published version, the importance to Creolistics of Oldendorp's thorough description of the language's grammar and usage in social contexts is difficult to overstate. Along with his later German-Negerhollands dictionary (*Criolisches Wörterbuch. erster zu vermehrender, und, wo nötig, zu verbessernder Versuch*), it may be considered a standard for subsequent similar works in the field. Christian George Andreas Oldendorp died of dropsy in Ebersdorf at the age of 67 on March 9, 1787.

Speakers and Linguistic Resources

Omaha-Ponca is the name linguists use for the language of the Omaha and Ponca peoples. *Umo^{n}ho^n* (Omaha) and *Pa^{n}ka* (Ponca, sometimes spelled Ponka) dialects differ only minimally, but are considered distinct languages by their speakers. Both tribes formerly inhabited areas near the Missouri River in northeastern Nebraska. The Omahas are still located in this area, with the tribal headquarters at Macy, Nebraska, but most of the Poncas were removed in 1878 to northern Oklahoma, around Ponca City. A smaller group of Poncas still resides in Nebraska. The Omaha-Ponca language is a member of the Dhegiha branch of Mississippi Valley Siouan, closely related to the Osage, Kansa, and Quapaw languages (for more detail on the genetic relationships of the Siouan languages, *see* **Siouan Languages**).

The Omaha and Ponca dialects are severely endangered, with only a few dozen elderly fluent speakers of Omaha in Nebraska and of Ponca in Oklahoma. However, many younger people have some ability to speak or understand the languages, and language classes at several schools and colleges in Nebraska and Oklahoma have had some success in promoting fluency among passive speakers and semispeakers, as well as in teaching the language to children and college students. Major linguistic resources on Omaha-Ponca include the monumental text collections of James Owen Dorsey (1890, 1891) and Dorsey's draft grammar and slip file, the ethnographic studies by Fletcher and LaFlesche (1911) and Howard (1965), Swetland's dictionary (1991), and an unpublished grammar by Koontz (1984). Several dissertations are currently in progress.

Sounds and Spelling

Traditionally, like other Native American languages, Omaha-Ponca was not written. Independently, both tribes recently adopted nearly identical spelling systems, similar to the orthography used by Fletcher and LaFlesche, but reading and writing Omaha-Ponca are still complicated by the existence of several other orthographies. In particular, the Dorsey materials, the largest source of texts in the language, are written in an idiosyncratic orthography that uses upside-down letters for unaspirated stops, '¢' for the dental

approximant, 'q' for the voiceless velar fricative, and 'c' for the voiceless alveopalatal fricative, among other unusual symbols. Most modern linguistic writings on the language use a transcription that represents tense unaspirated stops with a double letter, nasal vowels with a hook under the letter, and alveopalatal consonants with a hachek (č, š, ǰ, ž); a slightly modified transcription known as 'NetSiouan' is used for electronic communication. This has the effect that even those who are literate in Omaha or Ponca do not have easy access to most works on the language.

In this article, the orthography adopted by current school programs is used. The phonemic inventory of Omaha-Ponca, using this system, is shown in Table 1. Several sounds require explanation. The plain voiceless stops are lax following a fricative, tense elsewhere. Glottalized consonants, which are ejective or co-articulated with a glottal stop, are rare. The back nasal vowel is spelled *o*^{n} in Omaha and *a*^{n} in Ponca. Throughout this article, for convenience, the Omaha spelling is used. It is not entirely clear whether there is more than one phonemic back nasal vowel. Phonetic vowels varying in quality from [a^n] to [o^n] to [u^n] occur, but are probably allophonically conditioned. A vowel *o* is written in a few words of men's speech.

The most unusual sound in Omaha-Ponca is the consonant spelled *th*. This phoneme ranges apparently freely from [l] to a lightly articulated voiced dental fricative [ð]. Historically derived from **r*, it behaves more like a liquid than a fricative, frequently occurring in syllable-initial clusters following a voiced stop (bth, gth), for instance. Because of its similarity to the sound in the English word 'this,' it is spelled *th* in the Fletcher–LaFlesche orthography and in current educational orthographies. Other systems represent it variously as ¢ (Dorsey), ð (Siouanist/linguistic), or *dh* (NetSiouan).

Vowel length is distinctive in accented syllables (*ná*^{n} *a*^{n}*de* 'heart' vs. *ná*^{n}*de* 'inside wall'), but this contrast was not recognized by linguists until the 1990s and is still marked only sporadically in written materials. Nasality is also distinctive, but sometimes difficult to hear, especially for [i] vs. [i^n] adjacent to a nasal consonant or in final position. For instance, 'water' can be found written as either *ni* or *ni*^{n}. A downstep pitch accent occurs on the first or second syllable of the word, and is distinctive, as in *wathát*^{h}*e* 'food' and *wáthat*^{h}*e* 'table', though this may turn out to correlate with vowel length. Instrumental phonetic studies of Omaha-Ponca are lacking. It would be useful to have studies of the exact quality of the various stop series, *th*, and the suprasegmental features.

Morphology

Like other Siouan languages, Omaha-Ponca has complex verbal morphology but very little elaboration of other categories. There is no grammatical class of adjectives; concepts such as 'tall' are expressed by stative verbs. Adverbs, pronouns, and demonstratives are minor, uninflected categories. Nouns, other than those derived from verbs, generally contain no inflectional morphology. The exception is vocative and inalienable possessive marking of relationship terms:

wi-ko^n	'my grandmother'
thi-ko^n	'your grandmother'
i-ko^n	'his/her/their grandmother (sometimes also used by men)
ko^n-ho	'grandmother!' (male vocative)
ko^n-ha	'grandmother!' (female vocative)

Table 1 Phonemic inventory of Omaha-Ponca

Sound	*Labial*	*Dental*	*Alveopalatal*	*Velar*	*Laryngeal*
Stops and affricates					
Voiced	b	d	j	g	
Voiceless					
Plain	p	t	ch	k	'
Aspirated	p^h	t^h	ch^h	k^h	
Glottalized	p'	t'			
Nasals	m	n			
Fricatives					
Voiced		z	zh	gh	
Voiceless					
Plain		s	sh	x	
Glottalized		s'	sh'	x'	
Approximants	w	th			h
Vowels					
Oral	i e a (o) u				
Nasal	i^n a^n/o^n				
Long	(doubled letter, e.g., aa)				

Definiteness is marked by a series of articles that also code animacy, proximateness, position, movement, and/or plurality of the nominal that they follow. This complex definite article system is an innovation shared with other Dhegiha languages:

nu ak^{h}a	'the man (proximate)'
nu thi^{n}k^{h}e	'the man (obviative animate sitting)'
zho^n k^{h}e	'the stick (long, horizontal)'
zho^n t^{h}e	'the wood (stacked vertically)'

The verb is the locus of most of the grammatical information in the sentence. Besides pronominal prefixes identifying subject and object of the clause, the verb may contain prefixal instrumental, locative, dative, possessive, reflexive, suus (reflexive possessive), and vertitive (returning motion) markers, some of which can be obscured by phonological processes. Postverbal enclitics code plurality, negation, habitual or potential aspect, evidentiality, imperative and interrogative mode, proximateness, and other categories, some marked for person. There is no category of tense (in the following examples, the abbreviations are as follows: 1S, first-person singular; 1PL, first-person plural; AGT, agent; BEN, benefactive; REFL, reflexive; POTEN, potential; AUX, auxiliary).

a-ki-g-thize-ta-mi^{n}k^{h}e
1S.AGT-BEN-REFL-get-POTEN-1S.AUX
'I'll get (it) for myself'.

Omaha-Ponca is an active-stative language, meaning that verbs take one or the other or both of two sets of pronominal prefixes, an agent set and a patient sset. The regular prefixes are given in the following example (there are also several irregular conjugations):

	1S	**2nd person**	**3rd person**	**1PL**
Agent:	a-	tha-	Ø-	o^n-
Patient:	o^n-	thi-	Ø-	wa-

Intransitive verbs take one set or the other, depending roughly on their semantics, 'active' verbs taking the agent set as their sole argument, and 'stative' verbs taking the patient set:

Active verb, gthi^n 'sit':
agthi^n 'I sit' thagthi^n 'you sit' gthi^n 'he/she/it/they sit'
o^{n}gthi^n 'we sit'
Stative verb, sni 'be cold':
o^{n}sni 'I'm cold' thisni 'you're cold' sni 'it's cold'
wasni 'we're cold'

Transitive verbs take both an agent prefix for the subject and a patient prefix for the object, e.g., *o^n-thi-do^{n}bai* 'we see you'. There is a portmanteau form *wi-* for first-person subject with second-person object, and an additional patient prefix *wa-* for third-person plural or indefinite object.

Syntax

Syntactically, Omaha-Ponca is a head-marking, head-final language. Postpositions follow their nominal arguments, as in *tiútano^n k^{h}e di* 'in the yard' (literally, 'yard the in'). Modal and evidential auxiliaries are at the end of the clause, after the verb, as are imperative and question particles. Determiners are the rightmost element in the nominal phrase (determiner phrase) and other noun modifiers also follow the head noun (noun + clause + possessive + article):

wat^{h}é	tu	wiwíta	tho^n
dress	blue	my	the

'my blue dress'

Basic sentence word order is subject-object-verb, as in the following example (PROX, proximate; EVID, evidential):

[wahó^{n}thishige	ak^{h}a]	[shó^{n}gewi^n]	[gó^{n}tha-i-t^{h}e]
Orphan.Boy	the	horse one	want-PROX-EVID

'Orphan Boy wanted a horse.'

Full subject-object-verb (SOV) sentences are actually rather uncommon, however. All constituents except the verb are optional, so subject and/or object are often missing; a verb alone constitutes a full grammatical sentence. In addition, SOV order is far from rigid; it is not uncommon for a major constituent, such as the underlined phrase in the following example, to occur after the verb. Such postverbal phrases generally seem to be topics, but may sometimes be simply an afterthought:

M. S. izházhe	athí^n	nú ak^{h}á
name	had	man the

'The man was named M. S.'.

Because all participants are marked on the verb and all nominals are optional, it is possible to analyze Omaha-Ponca as a pronominal argument language, in the sense that the pronominal affixes on the verb are the true syntactic arguments of the clause, with nominal phrases (when they occur) being adjuncts. As in other languages, this analysis is controversial.

Relative clauses in Omaha-Ponca are internal headed, with the head noun contained within the clause. The head noun is indefinite (not marked with a definite article), whereas the clause is followed by an article appropriate to the head noun's role in the matrix clause:

[[shi^{n}nuda	no^{n}ba	uxpátheawathe]	ama]
dog	two	I.lose.them	the

'The two dogs that I lost'.

Various types of nominal and adverbial subordinate clauses also exist, sometimes also marked with an article:

[[that^{h}í] t^{h}e] úudo^{n}
you.arrive.here the good
'It's good that you're here'.

Usage: Gendered Speech and Dialects

Some aspects of Omaha-Ponca language differ by the gender of the speaker. Male/female speech forms play only a minor role in the grammar and lexicon of the language; however, they are of great cultural salience and occur with high frequency, including, as they do, forms of address, greetings, terms for certain relatives, speech act markers (command, exclamation, and question particles), and interjections (see the following examples). Gendered speech sometimes hampers language teaching and revival efforts; males in particular are wary of learning inappropriate speech patterns from a female teacher. For example, *aho!*, a greeting or interjection showing approval, is used only by males. Imperative enclitics (Example (1)) and relationship terms/vocative enclitics (Example (2)) provide additional examples:

(1) -ga (male)/-a (female), sometimes with stress shift:
o^{n}'í-ga/o^{n}'i-á 'give it to me' (male/female)

(2) zhi^{n}thé-ho 'older brother!'
(male; i.e., addressed by brother)
tinu-há 'older brother!'
(female; i.e., addressed by sister)

Differences between Omaha and Ponca varieties of the language are slight, and mostly involve recently innovated vocabulary, such as 'telephone' (Ponca *má^{n} a^{n}ze ut^{h}í^{n}* 'tapping iron' (originally 'telegraph') vs. Omaha *mó^{n}o^{n}ze íutha* 'talking iron'), or 'cup' (Ponca *uxpé zhí^{n}ga* 'little dish' vs. Omaha *niúthato^{n}* 'drink water in it'). Some words differ in meaning. For instance, *shó^{n}zhi^{n}ga* (literally 'small horse') means 'colt' in Omaha but 'puppy' in Ponca. *Shó^{n}ge* (originally 'dog') has shifted its meaning to 'horse' in both Omaha and Ponca, but the young-animal term derived from it retains its older meaning in Ponca. Such lexical differences are not necessarily absolute. Given the close contact between Omahas and Poncas, in many cases both forms may be known in both communities.

Phonological and grammatical differences between Ponca and Omaha have not been well researched. There is some indication that Ponca speakers retain the final *-i* of the proximate/plural, which present-day Omaha speakers drop in most environments, though ablaut shows that it is underlyingly present, as in Ponca *athái*, Omaha *athá* 'she/he/they go', from *athé* + *i*. However, given the small number of speakers recorded, this may be more an idiolectal than a dialectal difference. In general, speakers from the two communities have no trouble understanding each other.

The Sultanate of Oman is situated at the eastern end of the Arabian Peninsula. It borders on the United Arab Emirates, Saudi Arabia and Yemen in the west and south, and faces the Gulf of Oman in the north and the Arabian Sea in the east. One of the oldest states in the region, the Sultanate at one time extended along the Arabian Sea and included the island of Zanzibar and the enclave Gwadur in Pakistan. Several ethnic and linguistic groups in Oman today trace their origin to former Omani territories. In the 20th century, Oman's economy became based on oil revenue, but agriculture and fishing still play a significant role.

Similar to other gulf-states, a high proportion of the population of Oman is made up of expatriates; about 570 000 out of a total population of 2.9 million are not Omani nationals. This high figure is the result of the high number of foreign workers present in Oman, mainly from India, Pakistan, and Iran, who contribute to the linguistic diversity of the country.

The official language of Oman is Standard Arabic. Monolingual speakers of Arabic are in a diglossic situation, where Standard Arabic is used in formal and official contexts, as well as for written communication, but the local dialects of Arabic are used in less formal, spoken speech situations. The main local varieties of spoken Arabic used in Oman are Omani Arabic, Gulf Arabic, and Dhofari Arabic. In addition to monolingual Arabic speakers, many Omani are bilingual in Arabic and another language.

Up to the 1990s, literacy in Oman was low, especially away from the urban centers, and was lower among women than among men. As a result of campaigns to eradicate illiteracy launched in the 1990s, however, the literacy level has gone up over the last decade, from an adult literacy of 54.7% in 1990 to one of 74.4% in 2002. However, the imbalance between males (82%) and females (65.4%) persists in adult literacy. Literacy of youth, those between age 15 and 24 years, approaches 98.5% universal literacy.

In addition to Arabic, several modern South Arabian languages are spoken in the south of Oman: Jibbali (25 000 speakers), Mehri (15 000), Harsusi (1000–2000), and Hobyót (100). Similar to Arabic, they are Semitic languages, but they are distinct from Arabic, even though increasingly influenced by – and under pressure from – it.

On the mountainous Musandam peninsula on the Straits of Hormuz, cut off from the rest of the country by a part of the United Arab Emirates, Shihuh tribesman speak Shihhi (Kumzari), an Iranian language with strong influence from Arabic not yet fully described.

In urban areas and especially in coastal towns and the capital Muscat, Swahili is widely used, mainly by Zanzbaris who left East Africa after political unrest in the 1960s. Similarly, many Balochi (Balochi, Southern) speakers are Omanis originating from South Asia. In addition to foreign-born Omanis, recent foreign workers brought new languages to Oman, notably Bengali, Hindi, and Urdu, as well as Farsi.

The most widely taught foreign language is English, which is also used as a language of instruction in tertiary education. Radio Oman operates English-language networks, and there are several English-language newspapers.

Omotic Languages

R J Hayward

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 5, pp. 2872–2873, © 1994, Elsevier Ltd.

The Omotic languages constitute an indigenous Ethiopian family of the Afroasiatic phylum. They are spoken in the west and the southwest of the country, with the River Omo as a geographical locus, and from this the name derives.

Earlier opinion included Omotic within Cushitic, but subsequent to Fleming (1969), it has generally been regarded as an independent family. There is a well-founded division into North and South subfamilies. While the latter (comprising Hamar, Dime, and the Ari dialects) exhibit close internal affinities, there is greater diversity within Northern Omotic, the following groups being recognized: Gonga (Kafa varieties, Mocha, Nao, and Anfillo), Dizoid (Dizi varieties and Sheko), Mao varieties, Gimira (Benchnon and She), Ometo (an extensive cluster of

languages and dialects including Wolaitta, Dorze, Gamo, Gofa, Basketto, Male, Zayse, Koyra and, possibly, Chara), and Yemsa (an isolate). The greatest numbers of speakers belong to the Ometo, Gonga, and Ari groups, though accurate figures for speakers of the Omotic languages remain unrecorded.

Omotic languages exhibit many of the linguistic features typical of the area; they show especially strong typological affinities with East and Central (Agaw) Cushitic.

Syntactically: (a) They are strictly head-final, i.e., the verb is final, all nominal modifiers precede the noun, only postpositions occur, etc.; the morphology, moreover, is entirely suffixal. (b) There is no WH-movement, though, as with any focused constituent, WH-elements may be moved to sentence-initial position by means of a type of clefting operation. (c) Verbs in non-final (but non-subordinate) clauses commonly lack agreement, and function rather like 'serial verbs.' (d) Many Omotic languages have a case system which opposes a marked nominative in subject NPs to an unmarked absolutive form found in all other syntactic functions (complement of verb, copula, or postposition) as well as for citation purposes. (e) Contrastive argument structures of lexically related verbs (e.g., passives, reciprocals, causatives, etc.) are indicated by stem suffixes. (f) Tense and modal distinctions are carried by auxiliaries following the main verb.

Phonologically: Omotic languages share the following areal features: (a) The 'emphatic' obstruent series of Afroasiatic is represented by glottalized segments. (b) There is a symmetrical system of five peripheral vowels. (c) Length is pertinent for both consonants and vowels. (d) Pitch variation functions contrastively, though functionally many of the languages probably have 'tonal accent' rather than 'paradigmatic tonal' systems.

Going beyond areal typology, a range of Omotic languages exhibit phenomena that make it plausible to hypothesize four family-specific features, which, one assumes, are inherited from the protolanguage: (a) A root-structure constraint disallowing co-occurrence of palatal (ʃ, ʒ, tʃ, tʃ', dʒ) and non-palatal (s, z, ts, ts', (dz)) sibilants. (b) A nasal suffix accusative marker. (c) A three-term tonal system. (d) A lexical classification of nominals in terms of vocalic suffixes.

Certain Afroasiatic features have undergone simplification in Omotic: (a) Except in the case of human animates, formal agreement for nominal gender has been neutralized. (b) Number categories and morphology have been simplified; singulative forms are relic only, and each language employs just one plural formative. (c) No trace of the Afroasiatic Prefix Conjugation has survived.

Certain (groups of) languages have developed characteristics of some interest: (a) Benchnon Gimira has a system of six tones, which makes it unique within Africa. (b) The Ometo languages have evolved a distinct series of interrogative verb paradigms employed both for Yes/No and WH-questions.

Introduction

Oneida is a Native American language of the northern branch of the Iroquoian family, related to Seneca, Cayuga, Tuscarora, Onondaga, and, most closely, Mohawk. The homeland of the Oneida people is in central New York state. Migrations in the 1800s led to the three current communities of Oneidas on reservations in central New York and near Green Bay, Wisconsin, and a reserve near London, Ontario. A century ago most Oneidas spoke the language, but currently all Oneidas speak English and there are only small numbers of Oneida native speakers, primarily in Wisconsin and Ontario. All three Oneida communities sponsor efforts to preserve the language, but it is definitely endangered with the total number of fluent

languages and dialects including Wolaitta, Dorze, Gamo, Gofa, Basketto, Male, Zayse, Koyra and, possibly, Chara), and Yemsa (an isolate). The greatest numbers of speakers belong to the Ometo, Gonga, and Ari groups, though accurate figures for speakers of the Omotic languages remain unrecorded.

Omotic languages exhibit many of the linguistic features typical of the area; they show especially strong typological affinities with East and Central (Agaw) Cushitic.

Syntactically: (a) They are strictly head-final, i.e., the verb is final, all nominal modifiers precede the noun, only postpositions occur, etc.; the morphology, moreover, is entirely suffixal. (b) There is no WH-movement, though, as with any focused constituent, WH-elements may be moved to sentence-initial position by means of a type of clefting operation. (c) Verbs in non-final (but non-subordinate) clauses commonly lack agreement, and function rather like 'serial verbs.' (d) Many Omotic languages have a case system which opposes a marked nominative in subject NPs to an unmarked absolutive form found in all other syntactic functions (complement of verb, copula, or postposition) as well as for citation purposes. (e) Contrastive argument structures of lexically related verbs (e.g., passives, reciprocals, causatives, etc.) are indicated by stem suffixes. (f) Tense and modal distinctions are carried by auxiliaries following the main verb.

Phonologically: Omotic languages share the following areal features: (a) The 'emphatic' obstruent series of Afroasiatic is represented by glottalized segments. (b) There is a symmetrical system of five peripheral vowels. (c) Length is pertinent for both consonants and vowels. (d) Pitch variation functions contrastively, though functionally many of the languages probably have 'tonal accent' rather than 'paradigmatic tonal' systems.

Going beyond areal typology, a range of Omotic languages exhibit phenomena that make it plausible to hypothesize four family-specific features, which, one assumes, are inherited from the protolanguage: (a) A root-structure constraint disallowing co-occurrence of palatal (ʃ, ʒ, tʃ, tʃ', dʒ) and non-palatal (s, z, ts, ts', (dz)) sibilants. (b) A nasal suffix accusative marker. (c) A three-term tonal system. (d) A lexical classification of nominals in terms of vocalic suffixes.

Certain Afroasiatic features have undergone simplification in Omotic: (a) Except in the case of human animates, formal agreement for nominal gender has been neutralized. Introduction

Oneida is a Native American language of the northern branch of the Iroquoian family, related to Seneca, Cayuga, Tuscarora, Onondaga, and, most closely, Mohawk. The homeland of the Oneida people is in central New York state. Migrations in the 1800s led to the three current communities of Oneidas on reservations in central New York and near Green Bay, Wisconsin, and a reserve near London, Ontario. A century ago most Oneidas spoke the language, but currently all Oneidas speak English and there are only small numbers of Oneida native speakers, primarily in Wisconsin and Ontario. All three Oneida communities sponsor efforts to preserve the language, but it is definitely endangered with the total number of fluent

native speakers under 100. The Oneidas' name for themselves is *onʌyoteʔaˑkáˑ* 'people of the standing stone.' They also use the term *ukwehuˑwé* 'native people' for themselves and other Iroquoian people.

The oral traditions of the Oneidas support a wealth of stories and a rich set of ceremonies, shared with other members of the League of the Iroquois (also known as the Six Nations or *Haudenosaunee*). A written form of the language is a recent innovation. Jesuit missionaries established a writing tradition for the Mohawk language, and it was used by a few people for Oneida in the 19th century for personal letters, some records, and Bible translations. A linguistically based orthography was invented in the late 1930s and, slightly revised, has been in use since the 1970s for many language preservation materials.

Phonology

The Oneida phonemes are four oral vowels /i, e, a, o/, two nasal vowels /ʌ, u/, four resonants /l, w, y, n/, two stops /t, k/, a fricative /s/, two laryngeals /h, ʔ/, and a phoneme of vowel length. Two affricates are often analyzed as phoneme combinations /tsy, tshy/. The voicing of the stops and palatalization of the fricative are subphonemic processes conditioned by the following sound. Vowel length and pitch are distinctive, and the prosodic patterns produce one of the principal contrasts with the related Mohawk language. Patterns of epenthesis are another important contrast.

The sound system of the language is remarkable for a number of features: the small inventory of phonemes, the lack of labial sounds, and the presence of whispered syllables in a morphophonological process conditioned by placement within sentences. For example, the word for 'sugar' is *onutákliʔ* when it is followed by other words and *onutákehli* with the last syllable *-li-* whispered when it occurs at the end of a sentence or before a major phrase.

Morphology and the Lexicon

The morphology of the language is complex. There are only three clear word classes (nouns, verbs, and particles), but affixation is common with nouns and especially with verbs, which require, at minimum, pronominal prefixes and aspectual suffixes added to either simple or complex verb stems. There is a rich set of derivational processes that manipulate the basic argument structure of verbs. The process of noun incorporation, along with derivational morphemes such as reflexives, benefactives, causatives, and instrumentals, can build complex stems from simpler roots. There are also devices that convert nouns to verbs and verbs to nouns. Thus, derived forms can nest within others to create words of amazing length. In addition, there is a rich set of inflectional affixes for verbs. Suffixes supply aspectual and some tense inflections. One set of prefixes supplies a pronominal coding of one or two arguments (agent and patient) with number, person, and gender distinctions. There are two distinct feminine genders along with a masculine gender and a neuter gender that largely overlaps with one of the feminine genders. The other feminine gender is the unmarked gender in the singular, whereas the masculine is the unmarked gender in the plural. There are three categories of number: singular, dual, and plural. In addition verbs may have up to six of an additional set of 11 prefixes that supply various adverbial, directional, tense, mood, lexical, and syntactic functions. Words thus contain quite a few morphemes, and these morphemes are subject to quite a bit of alternation, conditioned by surrounding morphemes, by surrounding phonemes, and by accentuation patterns.

A couple of examples of Oneida verb forms demonstrate the template: Prefixes-Pronominals-Verb stem-Aspect suffix.

(1)	t	-ʌ́	-t	-k	-e	-ʔ
	back	-will	-toward	-I	-go	-ASP
	'I will come back'					

In (1), the verb stem *-e-* 'go' has a punctual aspect suffix *-ʔ-* and a pronominal prefix *-k-* that indicates 'first-person singular agent.' The sequence *tʌt* is a combination of three prefixes: *-t-* 'direction toward,' *-ʌ-* 'future tense,' and *-t-* 'returning.'

(2)	t	-huwati	-lihunyʌnít	-haʔ
	there	-they.AGT/them.PAT	-teach	-HABIT
	'school, they teach them there'			

The form in (2) is constructed as a verb, but can function as a noun. It consists of a complex verb stem *-lihunyʌniht-*, which is made of simpler components: an incorporated noun, *-lihw-* 'custom'; a verb root, *-uni-* 'make'; a benefactive derivational form that allows an argument role in the pronominal prefix for the receiver of the teaching, *-ʌni-*; and an instrumental derivational suffix that allows a focus on the means of teaching, in this case, the location, *-ht-*. When these four components are combined, certain sound rules apply: *-w-* is lost before *-u-*, *-i-* becomes a consonant before a vowel, and *-h-* is lost in the *-hth-* combination. The aspectual suffix *-haʔ* is 'habitual,' the pronominal prefix *-huwati-* indicates a third-person plural agent and patient, and the initial prefix *-t-* indicates location.

The noun morphology is simpler. A few nouns are uninflected, but most nouns have obligatory prefixes and suffixes on basic noun roots, and these affixes

mark the resulting words as nouns. The basic nominal prefixes can be replaced by possessive prefixes. There are a variety of locative suffixes, several pluralizing suffixes, a number of verb roots that function as adjective suffixes, and a few other suffixes. Many words that function as nouns in sentences, however, are not built from noun roots but instead are verb forms that produce descriptions used as nominals. In a few cases, it is difficult to tell whether a word is a noun or a verb.

(3) ka· -lút -eʔ
it -log -NOM
'log'

(4) ka -lut -o·kú
it -log -under
'under the log'

(5) ka -lu·t -ót -eʔ
it -log -stand -ASP
'tree, standing log, the tree is standing'

The prefix *ka-* is both a common noun prefix and a neuter pronominal prefix for verbs, and the suffix *-eʔ* is both a noun suffix and a verb suffix for the stative aspect.

As a result of the complex morphology, Oneida provides its speakers with enormous resources for word building. Undoubtedly not all of this potential is exploited, but many forms that are used are lexicalized, often with some semantic specialization, as in the verb for 'they teach them there,' which lexicalizes as 'school.' That lexicalization is sometimes marked by particular additional suffixes, but for many words there is no formal marking, only use, to indicate the lexicalization. Many functional nouns are thus created from formal verbs when a description becomes a name. This may account in part for the resistance the language has to borrowing words from English, which has surrounded and endangered the language for centuries.

Syntax

In the syntax, word order is not particularly rigid and intuitions of sentencehood are not strong. Particles and clusters of particles connect strings of predications and sometimes link to nominal arguments (which may appear formally to be verbs). The main arguments of the predication are encoded into the verb in the pronominal prefixes, and, if there is need to elaborate them, any elaboration tends to follow the predication. Particles and combinations of them provide discourse functions, subordination markers, deictics, emphasis, evidentials, and the pacing devices that are well developed in the oral tradition.

Scholarship

The academic study of the language includes some early text collection by Boas (1909) and analysis of verb stem classes by Barbeau (1915), but the real foundational work is by Lounsbury, based on fieldwork done in the Wisconsin community in the late 1930s and early 1940s. His work (Lounsbury, 1953), based on his M.A. thesis on Oneida phonology and his doctoral dissertation on verb morphology, set a framework not only for the future study of Oneida but for all the northern Iroquoian languages. Subsequent work by Karin Michelson has advanced the understanding of the sound system (Michelson, 1988) and the aspectual system (Michelson, 1995). The lexicon of the language is documented in two dictionaries, one based on fieldwork from the Wisconsin community (Abbott *et al.*, 1996) and one from the Ontario community (Michelson and Doxtator, 2002). A sketch of the linguistic structure of the language is available in Abbott (2000), and more complete grammars, both for reference and teaching, are in preparation. There are several text collections with linguistic analysis (Campisi and Christjohn, 1980; Abbott *et al.*, 1980; Michelson, 1981; Elm and Antone, 2000).

Community Work

Each of the three Oneida communities has a language preservation/recovery program to combat the endangered status of the language. Samples of the language, both written and spoken, are available on the websites of two of the Oneida communities: the Wisconsin community and the New York community. The language is being taught in tribal schools and in informal community classes. For the most part, the communities have adopted, since the 1970s, the writing system developed by Lounsbury, slightly modified from Lounsbury (1953). These programs have produced pedagogical materials, including some text collections (Abbott, 1982a, 1982b, 1983a, 1983b; Hinton, 1996) and word lists (Anton *et al.*, 1981; Anton, 1982), and include language material on their websites. The success of these programs in stemming the language loss over the last several decades has been fairly modest.

Charles Talbut Onions (pronounced like the vegetable, he said) is best remembered for his monumental (and posthumously published) *Oxford dictionary of English etymology* (1966), which gave etymologies for more than 38 000 English words.

Onions (*Companion to the English Language*) was born in Birmingham. He received a B.A. in French in 1892 and an M.A. in 1895, both from the University of London through Mason College in Birmingham. In 1895, he moved to Oxford and joined the staff of the *Oxford English dictionary* (OED). At the *OED*, he worked first under James Murray and then under Henry Bradley and W. A. Craigie, in particular on

SUB-Sz, Wh-Worling, and the letters X, Y, and Z. In 1914, he was appointed a senior editor. He composed the last entry in the *OED*, for *zyxt,* an obsolete Kentish dialect form of the verb 'to see.' He co-edited (with Craigie) the 1933 *Supplement*.

In addition to his work on the *OED*, Onions produced a survey of Shakespearian usage, *A Shakespeare glossary* (first edn., 1911); revised Henry Sweet's *Anglo-Saxon reader* (1922); and that same year took over the editing of the *Shorter Oxford English dictionary,* completing it in 1933.

After World War I, during which Onions served in British naval intelligence, he returned to Oxford, where he was first a lecturer in English and later a reader in English philology. In 1923, he was elected to fill the fellowship at Magdalen College left vacant by Henry Bradley's death. He also served as librarian of the college from 1940 to 1955. Despite his stammer, Onions was noted for his sharp and penetrating responses to questions of etymology and usage.

Onions served as the president of the Philological Society from 1929 to 1933, as the editor of *Medium Aevum* (the journal of the Society of the Study of Mediaeval Languages and Literature) from 1932 to 1956, and as honorary director of the Early English Text Society from 1945 to 1957.

Onions was made a Commander of the Order of the British Empire in 1934, and a Fellow of the British Academy in 1938. He married Angela Blythman in 1907; they had ten children.

Onomasiological Theory of Word Formation

P Štekauer, Prešov University, Prešov, Slovakia

© 2006 Elsevier Ltd. All rights reserved.

Overview

The term *onomasiology* goes back to Greek *ónoma* 'name.' An onomasiological approach to word formation (WF) encompasses several basic models whose common feature is procedure from concept/meaning to form. The onomasiological framework is cognitive, relating WF to conceptual thinking. The conceptual level establishes a link between the extralinguistic and linguistic levels of the naming process. Horecký (1983, 1999) explicitly presents this in his onomasiological chain: object–conceptual generalization–meaning–form.

In the short history of onomasiological research into WF, three main approaches have emerged. One of them is based on Dokulil's ideas; the second strictly separates the conceptual/semantic and the formal levels; in the third approach, any theory of WF is a byproduct of more broadly based onomasiological research into lexical semantics.

Dokulilean Tradition

While the basic principles of the onomasiological approach to WF were outlined by Dokulil as early as 1958, it is his later (1962) monograph that has become an onomasiological manifesto. The comprehensiveness, ingenuity, and depth of this work put it on a par with Marchand's *Categories* (1960). It anticipated a number of topics that emerged later in generative morphology.

It is assumed that a generalized picture of an extralinguistic object is processed in the human mind in accordance with the naming processes typical of a given language. While these processes (and their formal representations) differ from language to language, the conceptual basis of the act of naming is language-independent. Hence, Dokulil's central notion, the onomasiological category (1962: 29), is

SUB-Sz, Wh-Worling, and the letters X, Y, and Z. In 1914, he was appointed a senior editor. He composed the last entry in the *OED*, for *zyxt,* an obsolete Kentish dialect form of the verb 'to see.' He co-edited (with Craigie) the 1933 *Supplement*.

In addition to his work on the *OED*, Onions produced a survey of Shakespearian usage, *A Shakespeare glossary* (first edn., 1911); revised Henry Sweet's *Anglo-Saxon reader* (1922); and that same year took over the editing of the *Shorter Oxford English dictionary,* completing it in 1933.

After World War I, during which Onions served in British naval intelligence, he returned to Oxford, where he was first a lecturer in English and later a reader in English philology. In 1923, he was elected to fill the fellowship at Magdalen College left vacant by Henry Bradley's death. He also served as librarian of the college from 1940 to 1955. Despite his stammer, Onions was noted for his sharp and penetrating responses to questions of etymology and usage.

Onions served as the president of the Philological Society from 1929 to 1933, as the editor of *Medium Aevum* (the journal of the Society of the Study of Mediaeval Languages and Literature) from 1932 to 1956, and as honorary director of the Early English Text Society from 1945 to 1957.

Onions was made a Commander of the Order of the British Empire in 1934, and a Fellow of the British Academy in 1938. He married Angela Blythman in 1907; they had ten children.

Onomasiological Theory of Word Formation

P Štekauer, Prešov University, Prešov, Slovakia

© 2006 Elsevier Ltd. All rights reserved.

Overview

The term *onomasiology* goes back to Greek *ónoma* 'name.' An onomasiological approach to word formation (WF) encompasses several basic models whose common feature is procedure from concept/meaning to form. The onomasiological framework is cognitive, relating WF to conceptual thinking. The conceptual level establishes a link between the extralinguistic and linguistic levels of the naming process. Horecký (1983, 1999) explicitly presents this in his onomasiological chain: object–conceptual generalization–meaning–form.

In the short history of onomasiological research into WF, three main approaches have emerged. One of them is based on Dokulil's ideas; the second strictly separates the conceptual/semantic and the formal levels; in the third approach, any theory of WF is a byproduct of more broadly based onomasiological research into lexical semantics.

Dokulilean Tradition

While the basic principles of the onomasiological approach to WF were outlined by Dokulil as early as 1958, it is his later (1962) monograph that has become an onomasiological manifesto. The comprehensiveness, ingenuity, and depth of this work put it on a par with Marchand's *Categories* (1960). It anticipated a number of topics that emerged later in generative morphology.

It is assumed that a generalized picture of an extralinguistic object is processed in the human mind in accordance with the naming processes typical of a given language. While these processes (and their formal representations) differ from language to language, the conceptual basis of the act of naming is language-independent. Hence, Dokulil's central notion, the onomasiological category (1962: 29), is

defined as a basic conceptual structure in relation to its expression in a particular language.

The most common type of onomasiological category is relational. Dokulil pursues the binaristic tradition of morphosyntactic analysis by assuming, independent of Marchand's notion of WF syntagma, that this type consists of two basic constituents: an object is identified as a member of a conceptual class which is determined within that class. This establishes the basic naming scheme, onomasiological mark (the determiner)–onomasiological base (the conceptual class), representing an onomasiological structure. While the base is always simple, the mark may contain the determining (or 'motive') and the determined components, for example:

Cz. *roman-o-pis-ec*
novel-interfix-write-er

where *-ec* is the base, *roman* is the motive, and *-pis-* is the determined component of the mark. Omission of the determining component makes a naming unit more general (*writer*); omission of the determined component causes ambiguity of coinages (is, for example, *anthraxist* a person who '*terrorizes* people with anthrax,' '*produces* anthrax,' '*sells* anthrax,' '*studies* anthrax,' 'is *obsessed* with anthrax'?).

The relational type of onomasiological category is based on the 'relation' between the concepts standing for the motive and the base, respectively. There are four basic conceptual categories, SUBSTANCE, ACTION, QUALITY, and CIRCUMSTANCE. For example, *evening paper* relates the categories CIRCUMSTANCE and SUBSTANCE, *to redden* the categories QUALITY and ACTION. Within this general structure, more specific relations can be distinguished, based on semantic categories such as Agent, Patient, Bearer of Quality, Result, Possession, Origin, etc.

The transpositional type of onomasiological category is based on hypostatization of QUALITY or ACTION (*rapid* → *rapidity*, $fall_V \rightarrow fall_N$).

The modificational type onomasiological category includes various modifications of a concept, such as the formation of diminutives, augmentatives, change of gender, the young of animals, collectiveness.

Dokulil's work found a positive echo abroad, mainly in the countries of Central and East Europe. The major developments of Dokulil's theory are as follows.

An important step in the development of onomasiological theory is Horecký's multilevel model of WF (1983, 1989, 1999), including the conceptual, semantic, onomasiological, onomatological, and phonological levels. The cornerstone of his model is the semantic level. Horecký provides an inventory of semantic distinctive features, their relations, and hierarchical organization. This system is applied to the description of WF fields defined by the word class of the WF base and that of the resulting naming unit, e.g., deverbal substantives. Each WF field is dominated by a common semantic feature. The meaning of each naming unit is constituted by a bundle of semantic features.

The meaning facet of morphemes refers either to the object of extralinguistic reality (root morphemes) or to a (string of) semantic feature (affixes). Horecký (1994) distinguishes four types of meaning of a naming unit: (i) categorial meaning; (ii) invariant meaning, (iii) specific meaning, and (iv) lexical meaning. The first three meanings constitute the 'structural meaning' (given by the interrelation between onomasiological base and mark), and underlie the lexical meaning. For illustration, the respective meanings of Sl. *tretina* ($third_N$) are as follows: (i) desubstantival noun; (ii) 'abstract quality defined by the string of semantic features –HUM –CONCR –QUAL'; (iii) 'a third part of something,' (iv) 'one part of hockey match' (as one of its lexical meanings).

The gist of Štekauer's model (1996, 1998, 2001) is the concept of WF as a naming act performed by an individual speaker/writer. Horecký's onomasiological scheme is extended to reflect the crucial triad of WF relations, which exist between extralinguistic reality (object to be named), speech community (coiner), and WF, to emphasize the active role and cognitive capacity of a coiner. Each naming act responds to a specific naming demand of a speech community. This is reflected in the concept of productivity viewed as a competition between WF types falling within the same semantic category (Agent, Patient, Action, Instrument, etc.). The naming act is viewed as creativity within the productivity constraints, which means that (a) based on his/her conceptual processing of an object, a coiner may select from several possible onomasiological structures, and (b) there are usually several options for assigning morphemes to semantic categories constituting an onomasiological structure (Object–Action–Agent: *spiderweb researcher*, *web-researcher, spider-researcher*, *spiderwebbist*, *spiderweb-scholar*, *arachnologist*, *web-biologist*, *spider-webologist*, etc., for 'someone who explores spiderwebs').

All naming processes are accounted for by the same principle of matching the semantics of morphemes with the particular categories of onomasiological structure (Morpheme-to-Seme-Assignment Principle). The traditional semasiological classification of WF processes (compounding, prefixation, suffixation, etc.) is replaced by a consistent onomasiologal classification: five onomasiological types differ by the degree of complexity of and the relation between

the onomasiological and onomatological structures. In Type 1, each constituent of the ternary structure is assigned a morpheme (Object–Action–Agent: *wood-cut(t)-er*). In Type 2, the determining constituent of the mark is absent (Action–Instrument: *lock-pin*); in Type 3, the determined constituent of the mark is left unexpressed at the onomatological level (Result–Action–Agent: *honey*-θ-*bee*); in Type 4, the mark is unanalyzable (Negation–Quality: *in-consistent*). Type 5 (conversion) also has a conceptual foundation, and is defined as conceptual recategorization (Štekauer, 1996): an object to be named is processed and named from the perspective of a different conceptual category (e.g., $cheat_V \rightarrow cheat_N$ is a recategorization from ACTION to SUBSTANCE).

Separation Models

The best-known models of the 'separation theory' are Beard (1995) and Szymanek (1988). Inspired by Dokulil, Beard, and cognitive linguistics and psychology, Szymanek attempted to find an independent and reliable motivation for the set of derivational categories in a language. His cognitive grounding condition assumes that "[t]he basic set of lexical derivational categories is rooted in the fundamental concepts of cognition" (1988: 93). Szymanek's list includes 25 cognitive categories, such as Object, Substance, Person, Number, Existence, Possession, Action, Agent, Instrument, which, being basic, are reflected in derivational categories (e.g., the derivational category Agent Noun is grounded in the cognitive category Agent). Importantly, there are one-to-many and many-to-one relations between cognitive categories and derivational categories, and between derivational categories and their formal spell-out from which they are strictly separated.

Lexicosemantics-Centered Approach

Onomasiological research into lexical semantics, studying "the different lexical 'pathways' through which a particular concept has been designated" (Blank, 2001: 7) in various languages and/or the changes in the corresponding words over time, has a long tradition. It provides its WF offshoot with well-established and elaborate terminology. The basis for analysis is three Aristotelian associative principles: similarity, contrast, and contiguity, the latter being the relation between the concepts within a frame (e.g., the relations of time and space, cause and effect, agent and action) (Blank, 1998: 8–9).

The main task of a cognitive onomasiological theory of WF, as presented by Blank, is to account for the procedure leading from a concept to its linguistic expression by incorporating the related associative and cognitive principles. In the naming process, a base is chosen from one of the prototypical associations of a concept to be named (one which is represented by a word in a given language). The semantic gap between the base word and the named concept is bridged by another word or affix.

For illustration, the associative principle of similarity (roughly, SMALLER THAN DEFAULT) underlies It. *computerino* ('notebook'), where the semantic gap between the concept to be named (NOTEBOOK COMPUTER) and the base concept (COMPUTER) is bridged by the suffix *-ino*. An example of identity relation, realized by suffixation is It. *puro* 'pure' → *purezza* 'purity,' as both words are based on the same concept.

In compounds, two base concepts are combined; for example, It. *vagone letto* ('sleeping carriage') is based on the associative relations of similarity ('sleeping carriage' – 'carriage') and contiguity ('sleeping carriage' – 'bed').

Koch (2001) elaborates on these ideas to propose a three-dimensional universal model, interrelating (i) cognitive-association relations (identity, contiguity, metaphorical similarity, taxonomic similarity, taxonomic superordination, taxonomic subordination, cotaxonomic contrast, and conceptual contrast); (ii) formal relations (zero = semantic change (diachronically) or polysemy (synchronically), change in number, change in gender, diathesis, conversion, suffixation, prefixation, compounding, lexicalized syntagma, and idiom); and (iii) lexical stratification, i.e., the difference between native lexemes and borrowings. The model establishes a large number of potential combinations, not all of which are implemented in individual languages. For illustration, Sp. *carnicero* ('butcher') is represented as <contiguity.suffixation.stratum< Sp. *carniza* ('meat'), Engl. *pear-tree* as <taxonomic subordination + contiguity.composition. stratum< Engl. *tree* + *pear*; *sombrero* as <taxonomic subordination.zero.borrowing <Sp. *Sombrero* ('hat').

Onomasiology and Lexical Variation

D Geeraerts, University of Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

The Scope of Onomasiological Research

Although it has hardly found its way to the canonical English terminology of linguistics, the distinction between onomasiology and semasiology is a traditional one in Continental structural semantics and the Eastern European tradition of lexicological research. As Baldinger puts it, "Semasiology . . . considers the isolated word and the way its meanings are manifested, while onomasiology looks at the designations of a particular concept, that is, at a multiplicity of expressions which form a whole" (1980: 278). The distinction between semasiology and onomasiology, in other words, equals the distinction between meaning and naming: semasiology takes its starting-point in the word as a form, and charts the meanings that the word can occur with; onomasiology takes its starting-point in a concept, and investigates by which different expressions the concept can be designated, or named.

To grasp the range of onomasiology, one should realize that the two descriptions of onomasiology that Baldinger mentions are not exactly equivalent. On the one hand, studying 'a multiplicity of expressions which form a whole' lies at the basis of the traditional, structuralist conception of onomasiology, i.e., to the study of semantically related expressions (as in lexical field theory, or the study of the lexicon as a relational network of words interconnected by links of a hyponymical, antonymical, synonymous nature, etc.). On the other hand, studying 'the designations of a particular concept' opens the way for a contextualized, pragmatic conception of onomasiology, involving the actual choices made for a particular name as a designation of a particular concept or a particular referent.

Onomasiology and Lexical Variation

D Geeraerts, University of Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

The Scope of Onomasiological Research

Although it has hardly found its way to the canonical English terminology of linguistics, the distinction between onomasiology and semasiology is a traditional one in Continental structural semantics and the Eastern European tradition of lexicological research. As Baldinger puts it, "Semasiology . . . considers the isolated word and the way its meanings are manifested, while onomasiology looks at the designations of a particular concept, that is, at a multiplicity of expressions which form a whole" (1980: 278). The distinction between semasiology and onomasiology, in other words, equals the distinction between meaning and naming: semasiology takes its starting-point in the word as a form, and charts the meanings that the word can occur with; onomasiology takes its starting-point in a concept, and investigates by which different expressions the concept can be designated, or named.

To grasp the range of onomasiology, one should realize that the two descriptions of onomasiology that Baldinger mentions are not exactly equivalent. On the one hand, studying 'a multiplicity of expressions which form a whole' lies at the basis of the traditional, structuralist conception of onomasiology, i.e., to the study of semantically related expressions (as in lexical field theory, or the study of the lexicon as a relational network of words interconnected by links of a hyponymical, antonymical, synonymous nature, etc.). On the other hand, studying 'the designations of a particular concept' opens the way for a contextualized, pragmatic conception of onomasiology, involving the actual choices made for a particular name as a designation of a particular concept or a particular referent.

This distinction can be further equated with the distinction between an investigation of structure, and an investigation of use, or between an investigation of langue and an investigation of parole. The structural conception deals with sets of related expressions, and basically asks the question: what are the relations among the alternative expressions? The pragmatic conception deals with the actual choices made from among a set of related expressions, and basically asks the question: what factors determine the choice for one or the other alternative?

This second, usage-oriented (or if one wishes, pragmatic) form of onomasiology is related to two specific points of interest: differences of structural weight that may appear within onomasiological structures, and onomasiological change.

1. The importance of structural weight may be appreciated by considering semasiological structures first. Qualitative aspects of semasiological structure involve the following questions: which meanings does a word have, and how are they semantically related? The outcome is an investigation into polysemy, and the relationships of metonymy, metaphor, etc. that hold between the various readings of an item. Quantitative aspects of lexical structure, on the other hand, involve the question whether all the readings of an item carry the same structural weight. The semasiological outcome of a quantitative approach is an investigation into prototypicality effects of various kinds: prototypicality research is basically concerned with differences of structural weight among the members or the subsenses of a lexical item. The qualitative perspective is a much more traditional one in semasiological lexicology than the quantitative one, which was taken up systematically only recently, with the birth and development of prototype theory.

The distinction between the qualitative and the quantitative aspects of semantic structure (as we may loosely call them) can be extrapolated to onomasiology. The qualitative question then takes the following form: what kinds of (semantic) relations hold between the lexical items in a lexicon (or a subset of the lexicon)? The outcome, clearly, is an investigation into various kind of lexical structuring: field relationships, taxonomies, lexical relations like antonymy and so on. The quantitative question takes the following form: are some categories cognitively more salient than others; that is, are there any differences in the probability that one category rather than another will be chosen for designating things out in the world? Are certain lexical categories more obvious names than others? Again, this type of quantitative research is fairly new. The best-known example is probably Berlin and Kay's basic level model (Berlin and Kay, 1969; Berlin, 1978), which involves the claim that a particular taxonomical level constitutes a preferred, default level of categorization. The basic level in a taxonomy is the level that is (in a given culture) most naturally chosen as the level where categorization takes place; it has, in a sense, more structural weight than the other levels.

2. The distinction between a structure-oriented and a usage-oriented form of onomasiology extends naturally towards the study of onomasiological change. On the one hand, when we think of onomasiological change in a structural way, we will be basically interested in what may be called "lexicogenesis" – the mechanisms for introducing new pairs of word forms and word meanings. These involve all the traditional mechanisms that introduce new items into the onomasiological inventory of a language, like word formation, word creation (the creation of entirely new roots), borrowing, blending, truncation, ellipsis, folk etymology, and others. Crucially, the semasiological extension of the range of meanings of an existing word is itself one of the major mechanisms of onomasiological change – one of the mechanisms, that is, through which a concept to be expressed gets linked to a lexical expression. In this sense, the study of onomasiological changes is more comprehensive than the study of semasiological changes, since it encompasses the latter (while the reverse is obviously not the case).

On the other hand, if we think of onomasiological change in a usage-oriented way, the lexicogenetic perspective inevitably has to be supplemented with a sociolexicological perspective – with the study, that is, of how onomasiological changes spread through a speech community. Beyond merely identifying onomasiological mechanisms in the traditional etymological vein, we need to study how these mechanisms are put at work and how they may lead to overall changes in the habits of the language community. Classifications of lexicogenetic mechanisms merely identify the space of possible or virtual onomasiological changes; sociolexicology studies the actual realization of the changes.

The Contribution of Various Traditions of Research

The various traditions of lexical semantics have contributed in different ways to the study of onomasiology. The major traditions are the following:

- prestructuralist semantics, as dominant between 1870 and 1930, and as represented by the work of Paul, Bréal, Darmesteter, Wundt, and many others;

- structuralist semantics, as dominant between 1930 and 1960, and as represented by the work of Trier, Weisgerber, Coseriu, Lyons, and lexical field theorists at large;
- generativist and neogenerativist semantics, as originated in the 1960s, with the work of Katz and Fodor;
- cognitive semantics, as originated in the 1980s, and as represented by the work of Lakoff, Langacker, Talmy, and others.

Of these four traditions, all except the generativist/neogenerativist have made noteworthy contributions to the field of onomasiology.

1. Prestructuralist semantics – apart from coining the term *onomasiology* itself (Zauner, 1902) – has introduced some of the basic terminology for describing lexicogenetic mechanisms. Although basically concerned with semasiological changes, the major semasiological treatises from Bréal and Paul to Stern and Carnoy do not restrict themselves to strictly semasiological mechanisms like metaphor and metonymy, but also devote attention to mechanisms of onomasiological change like borrowing or folk etymology. (Compare Quadri [1952] for an overview of the tradition.) While the distinction between the two perspectives is treated more systematically in the structuralist era, attempts to classify lexicogenetic mechanisms continue to the present day. Different proposals may be found in the work of, among others, Dornseiff (1966), Algeo (1980), Tournier (1985), and Zgusta (1990).

2. The crucial contribution of structuralist semantics to onomasiology is its insistence, in the wake of De Saussure himself, on the distinction between semasiology and onomasiology. In the realm of diachronic linguistics, this division shows up, for instance, in Ullmann's classification of semantic changes (1962). More importantly, the bulk of (synchronic) structuralist semantics is devoted to the identification and description of different onomasiological structures in the lexicon, such as lexical fields, taxonomical hierarchies, lexical relations like antonymy and synonymy, and syntagmatic relationships.

3. There are three important contributions that cognitive semantics has so far made to onomasiology. First, cognitive semantics has drawn the attention to a number of qualitative onomasiological structures that did not come to the fore in the structuralist tradition. This shift holds true, on the one hand, for the development of the Fillmorean frame model of semantic analysis (Fillmore, 1977, Fillmore and Atkins, 1992). Frames constitute a specific type of syntagmatic structure in the lexicon that received little or no attention in the structuralist tradition. On the other hand, the seminal introduction of generalized metaphor research in the line of Lakoff and Johnson (1980) can be seen as the identification of figurative lexical fields: the ensembles of near-synonymous metaphors studied as conceptual metaphors constitute fields of related metaphorical expressions (just like ordinary semantic fields consist of ensembles of near-synonymous lexical items).

Second, cognitive semantics introduces a quantitative perspective into the study of onomasiological structures. As mentioned above, basic level research in the line of Berlin and Kay introduces the notion of salience into the description of taxonomical structures: basic levels are preferred, default levels of categorization.

Third, cognitive semantics introduces a quantitative perspective into the study of lexicogenetic mechanisms. Within the set of lexicogenetic mechanisms, some could be more salient (i.e., might be used more often) than others. Superficially, this increased use could involve, for instance, an overall preference for borrowing rather than morphological productivity as mechanisms for introducing new words, but from a cognitive semantic perspective, there are other, more subtle questions to ask: do the way in which novel words and expressions are being coined, reveal specific (and possibly preferred) ways of conceptualizing the onomasiological targets? For instance, do specific cultures have dominant metaphors for a given domain of experience (and could such dominant metaphors perhaps be universal – see Kövecses, 1990)?

In addition, cognitive semantics is gradually developing a pragmatic, usage-oriented form of onomasiological research in which the various factors that influence the onomasiological choice of a category for talking about a given referent, are being investigated. It has been shown, for instance (Geeraerts *et al.*, 1994, 1999), that the selection of a name for a referent appears to be determined by the semasiological salience of the referent, i.e., the degree of prototypicality of the referent with regard to the semasiological structure of the category, by the onomasiological salience of the category represented by the expression, and by contextual features of a classical sociolinguistic and geographical nature, involving the competition between different language varieties.

A Conceptual Map of Onomasiology

To conclude, we can summarize the relationship between the various aspects of onomasiology into a single comprehensive schema in Table 1.

Filling in the chart with the names of the research traditions that have made a dominant contribution

Table 1 A conceptual map of onomasiological research

	Qualitative approaches: what are the relevant phenomena?	*Quantitative approaches: which phenomena carry more weight?*
Synchronic structures	Research into lexical structures: *structuralist semantics* (plus cognitive semantics)	Research into onomasiological salience: *cognitive semantics*

A 'semantic operator' $\mathcal{O}$ maps one or more semantic entities $\vec{\alpha}$ to a resulting semantic entity $\mathcal{O}\vec{\alpha}$. This broad characterization subsumes such basic notions as predication, modification, coordination, and quantification. One may restrict the characterization so that the semantic entity α is the semantic value corresponding to a syntactic clause, or to a syntactic clause containing one or more gaps (in some sense), or in other ways. We here consider semantic operators from the perspective of the family of formal systems known as the λ-calculus. One reason to do so stems from the historical prominence of the λ-calculus in semantic investigations. A more forward-looking reason is that within this family, many questions arise

on formal grounds that are directly relevant to linguistic analysis, not only in semantics, but in all linguistic dimensions that involve compositional operations.

The historical roots of λ-calculus go back at least to Gottlob Frege (1879), who explicitly connects 'abstraction' with functions in the *Begriffsschrift,* §9. This intuitive idea was formalized by Alonzo Church (1941), and the introductory chapter of Church (1956) is in part an excursus on Frege's insights and methods. Contemporaneously, a formal system called 'combinatory logic' was introduced by Haskell Curry (see Curry and Feys, 1958; Curry, 1977) anticipated in earlier work by Moses Schönfinkel (1924). These systems have come to play a central role in a variety of basic problems in logic and computation: decision problems, recursive function theory, combinatory reduction systems, and theoretical computer science. They offer insights to a broad range of practical and theoretical issues in linguistics, as well. Our focus here will be on the variation introduced by different disciplines of resource sensitivity, and by different typing systems, and how these intrinsic parameters of variation connect with linguistic questions.

λ-terms

There are a variety of presentations of the system of λ-terms. (An excellent text is the book of Hindley and Seldin (1986); for a very readable introduction to connections with the theory of computation and the denotational semantics of programs, see Stoy (1981); Barendregt (1984) offers a comprehensive analysis; for other useful perspectives, see the books of Girard, Lafont, and Taylor (1989) and Krivine (1993). We draw freely on these works in the exposition that follows and the interested reader will find that the expositions of the subject they contain are well worth scrutiny.)

The most perspicuous is built up from a set V of variables by two operations: 'application,' which combines two terms M and N to make the term (MN); and 'abstraction,' which combines a variable x and a term M to make the term $(\lambda x.M)$, in which λx is called the 'abstraction operator' and M is its 'scope.' We use $x, y, z, \ldots$ for variables and assume that the variables represented by different letters are distinct unless explicitly identified. Similarly, we use capital roman letters ($M, N, P, Q, R, S, \ldots$) to represent λ-terms. The notation $M \equiv N$ means that M and N are the same λ-term. To reduce parentheses, we write $MN_1 \ldots N_k$ for $(\ldots(MN)\ldots N_k)$ and (nesting in the opposite direction) $\lambda x_1 \ldots x_k.M$ for $(\lambda x_1.(\ldots(\lambda x_k.\ M)\ldots))$.

An occurrence of a variable x in a term M is said to be 'bound' when it lies in the scope of an abstraction opertor of the form λx; otherwise, it is 'free.' Thus the variable x is free in the term x, in the term yx, but not in the term $\lambda x.x$. And the variable z has both bound and free occurrences in $(\lambda z.yz)z$ (while the occurrence of y is free). We write $FV(M)$ to denote the set of variables with free occurrences in the term M.

The intended interpretation of an application MN is that it represents the application of the function M to the argument N. The intended interpretation of an abstraction $\lambda x.M$ is that it forms that function which, when applied to an argument N returns the value M when free occurrences of x within M are interpreted as N. Thus, $\lambda x.x$ represents the 'identity' function: for any argument N, the intended interpretation of $(\lambda x.x)N$ is N itself. The term $\lambda x.y$ represents the 'constant' function whose value is always y: if we evaluate $(\lambda x.y)N$ by substituting N for free occurrences of x in y, the result is always y (since there are no free occurrences of x within the atomic variable y). Further examples: $\lambda xy.xy$ applies its first argument to its second argument (evaluation applied to the order *operator* · *argument*); $\lambda yx.xy$ applies its second argument to its first argument (evaluation applied to the order *argument* · *operator*); $\lambda yzx.zxy$ passes two arguments to z in reverse order (roughly as in English-like passive constructions, evaluation applies the second argument (z) to the third and applies the result to the first); $\lambda xzy.z(yx)$ applies its second argument to the result of applying its third argument to its first argument (roughly as in English subject-raising constructions); the similar term $\lambda zyx.z(yx)$ acts on its first two arguments to yield $\lambda x.z(yx)$, the *functional composition* of z and y; $\lambda x.xx$ applies its argument to itself.

Equivalent Terms and Alphabetic Variance

From the perspective of the intended interpretation, many distinct λ-terms in the presentation above are 'equivalent': $\lambda x.x$ represents the identity function, but $\lambda y.y$ and $\lambda z.z$ do so as well. Corresponding to this interpretive equivalence among such terms is a syntactic equivalence called a 'change of bound variables' or 'alphabetic variance' or 'α-conversion.' Intuitively, we start with a term of the form $\lambda x.M$ (or the occurrence of such a term in a larger term), replace the variable x in the abstraction operator with another variable (y, say), and replace all free occurrences of x in M with y (yielding a term we will denote by $[y/x]M$). But if this change of bound variables is to capture the correct notion of equivalence, it is essential to avoid two kinds of unwanted clashes.

In the first, starting with a term $\lambda x.M$ and changing to a term $\lambda y.[y/x]M$, we must ensure that M contains no free occurrences of y that would become bound in the shift to $\lambda y.[y/x]M$. For instance, $\lambda x.y$ is the constant function that returns y for any argument, but the putative alphabetic variant $\lambda y.[y/x]x \equiv \lambda y.y$ is the identity function, which is hardly equivalent (on the intended interpretation) to the function that yields y for any argument. Generalizing, we allow a change in bound variables from $\lambda x.M$ to $\lambda y.[y/x]M$ only when y is not in $FV(M)$, a restriction that prevents this form of inadvertent binding from arising.

The second kind of clash in the contemplated change from $\lambda x.M$ to $\lambda y.[y/x]M$ arises when M contains a free occurrence of x within the scope of an abstraction operator of the form λy: substituting y for free occurrences of x in M changes the essential structure of M, since free occurrences of x within the scope of λy are transformed by the substitution into bound occurrences of y. To see how to prevent such cases of inadvertent binding, let us walk through the several inductive cases of the substitution definition.

Substitution

Given a variable x, and two terms, N and M, we define substitution of N for free occurrences of x in M in a way that preserves the essential structure of the terms in question. The definition is inductive on the structure of M. If $M \equiv x$, then $[N/x]M \equiv N$ (substitute N for x); if M is an atom distinct from x, then $[N/x]M \equiv M$ (no occurrence of x to substitute for!); if $M \equiv PQ$, then $[N/x]M \equiv [N/x]P[N/x]Q$ (distribute the substitution across the application operation to the simpler arguments, which by the inductive assumption are defined); if $M \equiv \lambda\xi.M'$, then there are three subcases to consider: if $\xi = x$, then there are no free occurrences of x in $M \equiv \lambda x.M'$ and $[N/x]M \equiv M$; otherwise, if $\xi = y \neq x$, then $[N/x]\lambda y.M' \equiv \lambda y.[N/x]M'$ if $y \notin FV(N)$ (since no inadvertent bindings of y can arise by moving N inside the scope of λy in this case), but when $y \in FV(N)$, then $[N/x]\lambda y.M' \equiv \lambda z.[N/x][z/y]M'$, where z is not free in M' and not free in N. The final case addresses both forms of inadvertent binding: z must be chosen so that it is not free in M' (avoiding the change of bound variable problems) and is not free in N (so that no free variable in N can be bound in the course of inductive substitution). (A practical way to avoid the clashes that are possible under substitution is to adopt what Barendregt, [1984: §2.1.13 and Appendix C] calls the 'variable convention,' which requires that the set of bound variables and the set of free variables in any context are disjoint: under this assumption, we never need to consider alphabetic variants and the difficult and unintuitive final clause of the substitution definition above is simply preempted.)

β-conversion

Substitution plays a critical role as well in the characterization of β-conversion, a relation that models the evaluation of an application. We call an application of the form $(\lambda x.M)N$ a 'β-redex.' The 'contractum' of the redex $(\lambda x.M)N$ is the term $[N/x]M$. If a term P contains a particular occurrence of a β-redex Q and the term P' is the result of substituting the contractum of Q for that occurrence, we say that P β-contracts in one step to P' and write $P \rhd_1 P'$. We write $P \rhd R$ for the reflexive transitive closure of one-step reduction. A term that contains no β-redexes is said to be in 'β normal form.' These definitions raise a host of questions: Does every non-normal term reduce to a normal form? Can a term containing more than one β-redex reduce to different normal forms? If a term has a normal form, does every sequence of β-reductions result in this normal form?

In the system of λ-terms defined thus far, not every term reduces to a normal form. For example, consider the 'self-applicator' function $\lambda x.xx$, which takes an argument a and applies a to itself, yielding aa; if we apply the self-applicator to itself, we have $(\lambda x.xx)(\lambda x.xx)$, which β-reduces to $(\lambda x.xx)(\lambda x.xx)$ (same!). And we have $(\lambda x.((xx)x))\ (\lambda x.((xx)x)) \rhd_\beta ((\lambda x.((xx)x))(\lambda x.\ ((xx)x)))\ (\lambda x.((xx)x))$, where further steps of β-reduction lead to incremental growth. In these λ-terms, then, β-reduction does not reduce the number of λ-abstraction operators the term contains and these terms have no β-normal form. On the other hand, if a λ-term in this system has a normal form, the normal form is unique. This is a consequence of the celebrated 'Church-Rosser theorem,' which states that if a λ-term P is such that $P \rhd Q$ and $P \rhd R$, then there is a λ-terms S such that $Q \rhd S$ and $R \rhd S$. By this theorem, it is impossible for Q and R to be distinct β-normal forms, since if Q and R are both normal (and thus cannot undergo further β-reductions since they contain no β-redexes), $Q \rhd S$ only if $S \equiv Q$ and $R \rhd S$ only if $S \equiv R$, so that by the properties of $\equiv$ we have $Q \equiv R$, contradicting the premise that they are distinct. Finally, consider the λ-term T, with $T \equiv (\lambda y.z)\ ((\lambda x.xx)\ (\lambda x.xx))$, which applies the constant function $\lambda y.z$ (which returns z, by β-reduction, for any argument) to the self-applicator applied to itself. The term as a whole is a β-redex, but so is its argument. Consequently, the term offers alternative one-step β-reductions: one of them selects the β-redex whose abstraction operator is λy and yields the value z, which is β-normal; the other selects the argument

term $((\lambda x.xx)(\lambda x.xx))$, for which, as we have just seen, the input of β-reduction is identical to its output. Thus, T is a term that has a normal form (namely, z), but supports an infinite sequence of β-reductions (choose the second alternative at each step) that doesn't culminate with a β-normal form (since it doesn't culminate at all!). A system with these properties is called 'weakly normalizing': for any term with a β-normal form, its β-normal form is unique; but applying a series of β-reductions to a term need not culminate in its normal form, even when this normal form exists.

Alternative Presentations

The presence of an overt variable in each abstraction operator of the form $\lambda\xi$ makes the binding relation between the operator and the free variables of ξ within its scope relatively transparent. But as we have seen, this presentation provides many terms representing the same intended value (such as $\lambda x.x$ and $\lambda z.z$, with identical behavior with respect to β-reduction).

Congruence

One way to avoid this superfluity is to borrow a standard algebraic technique, regarding α-conversion as an equivalence relation and then showing that it is in fact a 'congruence' relation by proving that the basic operations on λ-terms respect it – that is, that if M and M' are alphabetic variants and N and N' are alphabetic variants, so are the applications MN and $M'N'$, the abstractions $\lambda x.M$ and $\lambda x.M'$ and the substitutions $[N/x]M$ and $[N'/x]M'$.

Nameless Terms

A more direct notational attack would be to replace free variables and their corresponding abstraction operators with a comparable notation providing a representation for every λ-term in which all alphabetic variants are represented by the same term. A system of this kind was devised by de Bruijn (1972). In this system, the standard set of variables represented by x, y, z, ... is replaced by the set of natural numbers 1, 2, 3, ..., and the standard abstraction operator consisting of λ followed by a standard variable (yielding such operators as λx and λy and λz) is replaced by the simple form λ. Following Barendregt's presentation, we define the system of Λ^*-terms inductively as follows: any natural number is a Λ^*-term; if P and Q are Λ^*-terms, so is (PQ); and for the abstraction step, if M is a Λ^*-term, so is λM. To interpret the result of adding the abstraction operator to a term, note that any occurrence of a variable k (i.e., a natural number) will be within the scope of n-many abstraction operators (for n a non-negative integer); if $k > n$, k is to be interpreted as a free variable; if $k \leq n$, then k is to be interpreted as a bound variable bound by k-th abstraction operator above it. On this interpretation, the Λ^* variables 1 and 2 are on a par with the standard x and y as free variables. But the identity function represented equivalently in the standard form by $\lambda x.x$ and $\lambda y.y$ is represented in the de Bruijn notation uniquely by $\lambda{\cdot}1$ (since the variable 1 is bound by the 1-st occurrence of the operator λ in whose scope it lies). If we replace the number 1 in $\lambda.1$ by any other natural number, the result is a constant function: thus, for the term $\lambda.2$, the variable 2 is free; so this Λ^*-term represents a constant function that returns 2 for any argument, just as the standard λ-term $\lambda y.z$ stands for the constant function that returns z for any argument. But whereas there are many equivalent standard λ-term representations of this function ($\lambda y.z$, $\lambda u.z$, $\lambda w.z$, ...), there is just one corresponding Λ^*-term. Although there is no formal operation in this system corresponding to α-conversion, an analog of β-reduction is still needed to evaluate β-redexes and the relevant notion of substitution has an arithmetical flavor, since it is necessary (*inter alia*) to increment the variable being substituted for each time the substitution operator traverses an occurrence of the λ-operator.

Combinatory Logic

A more radical idea, going back to Schönfinkel (1924) and developed much more fully by Curry and his collaborators and students, is to dispense with the abstraction operator altogether and replace it with a set of operators, a set of variables, and a set of postulates, which together form 'Combinatory Logic.' Surprisingly, two operators suffice. These operators are called K (*Konstant*) and S (*Substitution*) and their properties are defined by equations $\mathsf{K}xy = x$ and $\mathsf{S}xyz = xz(yz)$. In other words, K behaves like the λ-term $\lambda u.\lambda v.u$ (returning the first of its two arguments and throwing the second away), while S behaves like the λ-term $\lambda u.\lambda v.\lambda w.(u(w))(v(w))$. Consider now how to evaluate the term $\mathsf{SKK}x$: by the definition of S, this yields the term $\mathsf{K}x(\mathsf{K}x)$, which yields, by the definition of K, x itself. Thus, the combinator SKK behaves like the λ-term $\lambda x.x$. What about other λ-terms? We proceed inductively (inside out), using the following clauses: (1) $\lambda x.x = \mathsf{I} = \mathsf{SKK}$; (2) $\lambda x.M = \mathsf{K}M$ if $x \notin FV(M)$ (which covers $\lambda x.y$ as a special case); (3) $\lambda x.MN = \mathsf{S}(\lambda x.M)(\lambda x.N)$. As an example, take the term $\lambda x.\lambda y.yx$ that maps an element x to its 'type-lifted' analogue. Eliminating innermost occurrences

of the λ-operator first, we have $\lambda y.yx = \mathsf{S}(\lambda y.y)(\lambda y.x) = \mathsf{SI}(\mathsf{K}(x))$. Substituting this result for $\lambda y.yx$ in $\lambda x.\lambda y.yx$ yields $\lambda x.\mathsf{SI}(\mathsf{K}x)$, which translates to $\mathsf{S}(\lambda x.\mathsf{SI})\ (\lambda x.\mathsf{K}x)$, which in turn translates to $\mathsf{S}(\mathsf{K}(\mathsf{SI}))\ (\mathsf{S}(\mathsf{KK})\mathsf{I})$ (in several steps) (which is further reducible if we would like to replace I by SSK). If we apply this to an entity f, we obtain $(\mathsf{K}(\mathsf{SI})f)((\mathsf{S}(\mathsf{KK})\mathsf{I})f)$, which itself reduces to $(\mathsf{SI})((\mathsf{KK})f)(\mathsf{I}(f)))$. Applying this to a second argument g yields $\mathsf{I}g(((\mathsf{KK})f(\mathsf{I}(f)))g)$, which reduces to $g(\mathsf{K}fg) = gf$.

From a linguistic point of view, it is noteworthy that the 'operator / bound variable' syntax of the standard form of the λ-calculus is not required to express its fundamental concepts. In particular, in the standard presentation of λ-terms, the 'operator / bound variable' relation is unconstrained: we can add, for any variable x, the abstraction operator λx to any term and form a term. As a result, discontinuous (long-distance) binding is built into the syntax of these standard λ-terms from the outset. In the theory of combinators, all communication between arguments and operators is local (just as it is in the standard account of β-conversion). Local control opens the way to more sensitive discrimination in dealing with discontinuous dependencies. Early transformational accounts of discontinuous dependencies treated them in a way that allowed movement across an 'essential variable.' Non-transformational accounts of discontinuous dependencies – in GPSG, Combinatory Grammar, HPSG, LFG, Type Logical Grammar – have all tacitly adopted a recursive specification of discontinuty and it is explicitly recursive in the LFG-centric idea of 'functional uncertainty' and the modally-licensed postulates of Type Logical Grammar.

Parameters of Variation

The different perspectives sketched above present a basically uniform general system from different points of view. But this general system is the source of a family of quite distinct systems that arise by fixing specific values along particular dimensions. Here we examine three of these dimensions. The first involves the addition of new operators apart from application and abstraction. The second involves assigning 'types' to λ-terms, and serves as a source of variation because of different ways in which the external system of types and λ-terms interact. Our third dimension involves 'resource-relations' within λ-terms themselves, and thus deals with intrinsic properties of λ-terms themselves (although the properties in question are hardly restricted to λ-terms).

Additional Operators

A standard convention in the study of λ-terms is to assume that restricting applications and abstractions to act on one term at a time is not a restriction in principle, in view of the 1-1 correspondence between functions that map a pair of elements $\langle a, b\rangle$ to a value v and functions that map the element a to a function that maps b to the value v. For example, take the function that maps the pair $\langle a, b\rangle$ to their sum $a + b$. Instead of doing this in one fell swoop, we can start with a and get back the function $\lambda y.a + y$ (that is, the function *increase-by-a*), then apply this to b (in the form $(\lambda y.a + y)b)$), which normalizes to $a + b$, the exact value we reached from the pair. It is possible to incorporate this reasoning explicitly into the λ-calculus by introducing operators apart from application and abstraction (though it is also possible but not always convenient to *define* such operations by means of λ-terms).

The most basic case is the addition of a binary product operator $\times$, together with projection operators π_0, π_1, defined so that $\pi_0\ (A \times B) = A$, $\pi_1\ (A \times B) = B$, and $(\pi_0(A) \times \pi_1(A)) = A$. Taking '+' as a primitive, and using these definitions, one may show that $(\lambda z.\pi_0(z) + \pi_1(z))\ \langle 3,5\rangle = ((\lambda x.(\lambda y.x + y))(3))(5)$ in the sense that they both normalize (given the equation for the product operator) to $3 + 5$. If we reverse the order of arguments in such cases and at the same time reverse the order of abstraction operators, both cases normalize to the same value: $((\lambda x.(\lambda y.x + y))(3))(5) \rhd 3 + 5 \lhd ((\lambda y.(\lambda x.x + y))(5))(3)$. In just the same way that we smuggled some arithmetical notation into these terms, we can introduce the characteristic application/abstraction structure of λ-calculus with many systems (including the system of natural language expressions).

Thus, in the λ-calculus, there are interesting correspondences to be observed between cases involving multi-argument functions and cases in which functions act on one argument at a time, as well as correspondences between functions that act on several arguments successively and functions that act on a permutation of the order of these arguments. These questions bear directly on linguistic attempts to model syntactically such phenomena as discontinuous dependencies, the 'non-standard' constituent structure found in intonational phrasing, coordinate structures, and clitic structures. Rigid approaches to constituent structure are not naturally adaptable to the analysis of such phenomena, and require the introduction of theoretically *ad hoc* 'restructuring rules' that manipulate constituent structure (often under the assumed control of particular lexical expressions); on the other hand,

while the full generality of the flexible possibilities of the λ-calculus provides a capacious framework to investigate these issues, it may offer more equivalences than are actually wanted. A reasonable formal balance would be to make flexible constituency a choice, but not a requirement (as in multi-modal type logical grammar [Moortgat, 1997); [Oehrle, in press]).

Types

The basic system of λ-terms that we have focused on thus far is type-free in the sense that the formation rules for application and abstraction enforce no restrictions on the properties of their input and output terms. This has some advantages: there is a single identity operator $\lambda x.x$ (aka $\lambda.1$ in the nameless notation or I as a combinator), rather than a distinct identity function for each set (as in set-theoretical treatments of functions). And it has some disadvantages: certain combinations allowable in the type-free system, such as $((\lambda x.xx)\ (\lambda x.xx))$ have no β-normal form. Analogous choices are important in a number of places in natural language analysis, where 'type' is closely related to the notion 'category' and where grammatical composition is standardly taken to be category-dependent.

Church Typing

One way to assign types to λ-terms originates with Church (1940), with sources in earlier work going back to Russell's ramified theory of types. We first define a system T of types generated by a set of basic types t. Any element τ of t is a type in T; if τ_1 and τ_2 are elements of T, so is $\tau_1 \rightarrow \tau_2$. For example, if $T = \{np, s\}$, we have basic types np, s, and such complex types as $s \rightarrow s$ (compare sentence modifiers), $np \rightarrow s$ (a simple predicate), $(np \rightarrow (np \rightarrow s)$ (a 2-place predicate), $(np \rightarrow s) \rightarrow s$ (a monadic quantifier). Every atom a is assigned a type t (not necessarily an atomic type!). We write $M : t$ to indicate that a term M has been assigned type t.

The rules for application and abstraction are modified so that every complex expression is also assigned a type. Application is stated so that an application $(MN) : \beta$ can be formed only from $M : \alpha \rightarrow \beta$ and $N : \alpha$. (In this transition, the types $\alpha \rightarrow \beta$ and α combine to yield the type β.) Similarly, if $x : \alpha$ is a variable of type α and $M : \beta$ is a term of type β, we can form the abstraction $(\lambda x : \alpha.M : \beta) : \alpha \rightarrow \beta$.

A consequence of Church's typing system is that there is no longer a single identity function represented by the equivalence class that includes $\lambda x.x$, $\lambda y.y$, $\lambda z.z$, ... Instead, for each typed variable $x : \alpha$, there is an identity function $\lambda x : \alpha.x : \alpha$ and if the types α and β are distinct, then $\lambda x : \alpha.x : \alpha$ and $\lambda y : \beta.y : \beta$ are distinct identity functions: they act on distinct types. This usage accords with the definition of functions in algebra and category theory, where there is a particular identity function 1_A for every set or category A, but no general identity function that acts on any object whatsoever. But it conflicts with the intuition that such a general operation is a reasonable one.

A second consequence of Church's typing system is that self-application is impossible. For any typed λ-term $f : \alpha$, there can be no term $(f : \alpha f : \alpha)$, because the type restrictions imposed on the formation of applications require that in the first occurrence of $f : \alpha$, α be a type of the form $\alpha \rightarrow \beta$. But as we have defined types, this is impossible.

As a result of these restrictions, however, the system of λ-terms with Church-typing are 'strongly normalizing': every term has a β-normal form and every sequence of β-reductions starting with a given term M terminates with the normal form of M after a finite number of steps.

As we will see below, Montague's celebrated system of Intensional Logic is an extension of Church's typing system.

Curry Typing

Church's type system assigns a fixed type to every atom. And the type requirements imposed on the components of well-formed complex types preclude the formation of self-application types. Curry proposed an alternative (clearly set forth in Hindley, 1997), in which the set of terms is the same as in the general (type-free) system. Some of these terms are typable, others are not. Types are assigned to terms by a system of 'type-inference' stated over 'sequents' of the form $\Gamma \mapsto M : \tau$, where Γ is a set of type-declarations of the form $x : \alpha$ (associating an atom x with a type α), and $M : \tau$ pairs a term M with a type τ. The antecedent Γ is called a 'context.' And two contexts Γ_1 and Γ_2 are said to be 'consistent' when their union does not contain both $x : \alpha$ and $x : \beta$ with $\alpha \neq \beta$. We write $\Gamma - x$ to denote the result of removing any element of the form $x : \alpha$ (if there is one).

Curry's type assignment system starts with an infinite set of axioms: for any variable x and type α, the sequent $\{x : \alpha\} \mapsto x : \alpha$ is an axiom. Then there are two inference rules, for application and abstraction, respectively. The application rule states that if $\Gamma_1 \mapsto M : \alpha \rightarrow \beta$ and $\Gamma_2 \mapsto N : \alpha$, then $\Gamma_1 \cup \Gamma_2 \mapsto (MN) : \beta$ if $\Gamma_1 \cup \Gamma_2$ is consistent. The abstraction rule states that if $\Gamma \mapsto M : \beta$, then $\Gamma - x \mapsto \lambda x.M : \alpha \rightarrow \beta$, if Γ is consistent with $\{x : \alpha\}$.

These inference rules depend on properties of the contexts involved. But we are particularly interested

in type assignments that make no particular assumptions – that is, the empty context. For example, no particular assumptions are needed to prove that the term $\lambda x.x$ can be assigned any type of the form $\alpha \rightarrow \alpha$: we start with the conclusion of the desired proof, which takes the form $\emptyset \mapsto \lambda x.x : \alpha \rightarrow \alpha$, and this sequent can be proved using the abstraction rule from the sequent $x : \alpha \mapsto x : \alpha$, which is itself an axiom. To prove that the application of the identity function to itself is typable, we start with the sequent $\emptyset \mapsto (\lambda x.x)\ (\lambda x.x) : \alpha \rightarrow \alpha$, which is provable if we can prove both $\emptyset \mapsto \lambda x.x : (\alpha \rightarrow \alpha) \rightarrow (\alpha \rightarrow \alpha)$ and $\emptyset \mapsto \lambda x.x\alpha \rightarrow \alpha$ (where the empty antecedents are clearly consistent). But we've just seen how to carry out these two sub-proofs – in one of them, the variable x is associated with the type α; in the other, the variable x is associated with the type $(\alpha \rightarrow \alpha) \rightarrow (\alpha \rightarrow \alpha)$.

On the other hand, the term $\lambda x.xx$ is not typable at all. If it were, we could prove it by proving $\emptyset \mapsto \lambda x.xx : \alpha \rightarrow \beta$, which is provable if it is provable that $\{x : \alpha\} \mapsto xx : \beta$. And this is provable if we can find consistent contexts Γ_1 and Γ_2, with $x : \alpha \rightarrow \beta$ in Γ_1 and $x : \alpha$ in Γ_2. But this is impossible: any solution of the final requirement is inconsistent, since it requires that x be associated with distinct types. This shows that not every type-free λ-term is typable.

Any term that is well-typed in Church's system is typable in Curry's system of type assignment. And to every way of typing a term in Curry's system, there is a corresponding Church-typed term. A basic difference, however, is that Curry's system allows a single term to be typed in more than one way. This is the essential property of *polymorphic type systems*, which have played an increasingly important role in the semantics of programming languages. For example, for important practical reasons, integers (type int) and real numbers (type float) are distinct types in many programming languages, but we would like to be able to combine integers with reals in arithmetical operations (accommodated by shifting objects of type int to corresponding objects of type float) and then to print the result (conversion again to type string) in decimal notation – distinct from the underlying representation of either type of number in the machine language. There is a direct analogy here to what has been called 'coercion' in natural language semantics, involving shifts between mass and count interpretations of nouns or various aspectual categories. From a linguistic perspective, Curry's system – which is not rigid on the assignment of types to underlying constants but does demand overall consistency – is closer to natural language analysis than Church's system, because in natural language (roughly speaking) global consistency is more highly valued than rigid adherence to local values.

Resource-sensitivity

In the constant function $\lambda y.x$ (where we take y and x to be distinct atoms), there is no free occurrence of y in x. In such a case, when the variable associated with an abstraction operator has no free occurrences within its scope, the abstraction is said to be 'vacuous.' In the identity function $\lambda y.y$, the abstraction operator λy binds exactly one occurrence of the associated variable y within its scope. A case of this kind is said to be 'linear.' There is no standard term that applies to the case in which an abstraction operator binds more than one occurrence of the associated variable within its scope, as with the combinator S, which is expressed in the λ-calculus by a term of the form $\lambda x.\lambda y.\lambda z.xz(yz)$, where the abstraction operator λz binds two occurrences of the associated variable z within its scope. These same distinctions show up in a wide variety of contexts and data structures, from the differentiation of 'sets,' 'multisets,' and 'sequences,' to the study of 'relevance logic' and 'linear logic,' to graph theory (in the distinction between 'graphs,' which allow at most one edge between nodes, and 'multigraphs,' which allow distinct edges between a single pair of nodes), and probability theory (in the distinction between 'sampling with replacement' and 'sampling without replacement'). Interest in subsystems of λ-terms or combinators weaker than the full system has grown increasingly and escalated sharply in recent years. (For further discussion, see Morrill and Carpenter, 1990; van Benthem, 1995; Moortgat, 1997 and Oehrle, 2003. Steedman's Combinatory Categorial Grammar 2000) is based on a resource-sensitive fragment of combinatory logic.)

Church observed that the application $(\lambda y.z)$ $((\lambda x.xx)\ (\lambda x.xx))$ is unusual in having a β-normal form (namely, z) and allowing a non-terminating series of β-reductions (namely, the series that arises by always choosing to reduce on the subterms $(\lambda x.xx)$ $(\lambda x.xx)$, which reduces to itself). Such a case, where a term has a normal form but has a subterm with no normal form, arises only if vacuous abstraction is allowed.

Resource-sensitivity is not restricted to questions of occurrence or multiplicities (as in the differentiation of vacuous, linear, and multilinear binding just discussed), but also involves the equivalence or differentiation of structural relations, such as 'associativity' and 'order.' These properties are universal for binary operations, in the sense that any binary operation can be characterized in part by its treatment of resources. Not surprisingly, the resource-sensitive perspective that has one of its sources in the study of λ-terms has many applications to linguistic analysis.

Linguistic Applications of the λ-calculus

The λ-calculus is applicable to any system in which the notions of function or operation play a central role. In the case of natural language analysis, there are two basic perspectives one may take, in view of the fact that language is a 'multi-dimensional' phenomenon in which a variety of subsystems – segmental structure, syntactic form, intonational structure, semantic and pragmatic interpretation – play interactive and mutually-constraining roles. In such a case, one may consider the applicability of the λ-calculus to the individual subsystems, or examine how it can be used to regulate the interaction of these subsystems. In the exposition and examples to follow, we freely shift between these two perspectives.

The Extensional Subsystem of Montague's PTQ

A number of important questions regarding syntactic categories, semantic types, and semantic interpretation crystallized around the publication of a series of papers in the late 1960s and early 1970s by Richard Montague, which showed how a number of difficult problems in natural language semantics can be modeled (to a first approximation) in a possible-worlds setting. (Montague's linguistic work is contained in Montague (1974).) Before considering the full intensional system, we first examine its extensional subsystem, which is a Church-typed form of higher order λ-terms.

The extensional type system is built up from atomic types e ('entity') and t ('truth-value') and is closed under a binary operation $\langle -, - \rangle$ (which plays the same role here as the binary operation $\rightarrow$ introduced above in the discussion of Church's type system). The language associated with these types is the smallest set containing: 1. constants C_a and variables V_a for each type a; 2. the λ-term $\lambda x.\alpha$ of type $\langle b, a\rangle$, whenever x is in V_b and α is an expression of type a; 3. the application $\alpha(\beta)$ of type a, whenever α is an expression of type $\langle b, a\rangle$ and β is a term of type b; 4. the equality $\alpha = \beta$ of type t, whenever α and β are of the same type; 5. the standard truth-functional operations from propositional logic ($\neg -$, $- \vee -$; $- \wedge -$; $- \rightarrow -$; $- \leftrightarrow -$), which combine with one or more expressions of type t to form an expression of type t; 6. the (higher-order) quantifiers $\bigvee$ and $\bigwedge$ which combine with a variable u (of any type) and an expression ϕ of type t to make the existential quantification $\bigvee u\phi$ and the universal quantification $\bigwedge u\phi$.

To interpret this language, we need a nonempty set E of entities, the set $\{0,1\}$ of truth-values (0 for false, 1 for true), and we need to specify, for each type a, the set D_a of possible interpretations of expressions of type a: $D_e = E$, $D_t = \{0,1\}$, and $D_{\langle b,\ a\rangle}$ is the set of function with domain D_b and codomain D_a. In addition to these constraints, we need a function F that assigns to each constant c of type a an interpretation in D_a and a function g that assigns to each variable u of type a an interpretation in D_a. Looking back to the extensional language defined above, we can interpret it in the following way: (1) If c is a constant, its interpretation is $F(c)$ and if υ is a variable, its interpretation is $g(\upsilon)$. (2) The abstraction $\lambda x.\alpha$ of type $\langle b, a\rangle$ is interpreted as a function $h : D_b \rightarrow D_a$ from D_b to D_a; this function acts on an argument b in D_b and associates it to the entity in D_a which is the interpretation of α that differs possibly from its interpretation relative to F (which assigns interpretations to the constants in α) and the assignment function g (which interprets the free variables α) only by fixing the value of the variable x in α to the argument b. (This is a model-theoretic analogue of β-reduction: whereas we think of β-reduction as manipulating symbols 'syntactically,' by replacing one symbol with another in the course of carrying out substitution, the model-theoretic analogue simply identifies semantic values); (3) given α of type $\langle b, a\rangle$, interpreted as a function α' from D_b to D_a and given β of type b with interpretation β' in D_b, the interpretation of the application $\alpha(\beta)$ is simply the application of the function α' to the argument β', which yields $\alpha'(\beta')$ of type D_a; the remainder of the clauses are standard.

We now introduce an 'object-language,' whose elements are interpreted categorized expressions. To indicate that an expression **e** of the object-language is associated with interpretation i and type T, we write **e**:i:T. Each syntactic category C is associated with a semantic type $T(C)$; and each object-language expression belonging to C will be interpreted as an object of the semantic type $T(C)$. We assign to each 'lexical' object-language expression **e** a category and an interpretation i consistent with its category (and indicate the association between expression and interpretation by writing **e**:i). Each rule that combines expressions $e_1, \ldots, e_k$ into a complex expression $E(e_1, \ldots, e_k)$, also assigns an interpretation E' $(e'_1, \ldots, e'_1)$ based on the interpretations $e'_1, \ldots, e'_k$ of the syntactic components $e_1, \ldots, e_k$. Finally, to make the exercise more interesting, we assume that the set of categories is 'structured': we begin with some 'atomic categories' (atomic for purposes here, at least); then we close the set of categories under a binary operation $-/-$, so that whenever A and B are categories associated with semantic types $T(A)$ and $T(B)$, respectively, then A/B is a category associated with the semantic type $\langle T(B), T(A)\rangle$. As basic categories, we choose: S ('sentence'), with $T(S) = t$; Nm ('name'), with $T(Nm) = e$; CN ('common noun'), with $T(CN) = \langle e, t\rangle$.

We assume no lexical element of the category S, but we admit such lexical names as $jan{:}j^e{:}Nm$ and $lee{:}l^e{:}Nm$ (where j^e and l^e are constants of type e) and such lexical common nouns as $teacher{:}tch^{\langle e,t\rangle}{:}CN$ and $student{:}st^{\langle e,t\rangle}{:}CN$. We also assume the existence of lexical elements belonging to various complex categories. For example, we may allow the lexical element $sneezes{:}snz^{\langle e,t\rangle}{:}S/Nm$, the lexical element $everyone{:}\lambda P^{\langle e,t\rangle}\forall x^e.P(x){:}S/(S/Nm)$, and the lexical element $every{:}\lambda Q^{\langle e,t\rangle}\ \lambda P^{\langle e,t\rangle}\ \forall x^e.(Q(x) \rightarrow P(x)){:}(S/(S/Nm))/CN$.

If α is an expression whose syntactic category is of the form A/B and β is an expression whose syntactic category is B, then α and β are compositionally compatible: we know that if it is in fact possible to combine α and β syntactically, then there is available a syntactic category (namely, A) and a compatible interpretation $(\alpha'(\beta'))$ that can be assigned to A. But in Montague's syntactic category system (unlike other forms of Categorial Grammar), the structure of syntactic categories themselves does not determine how two compositionally compatible expressions can combine. As a consequence, it is necessary to state rules of combination for various pairs of syntactic categories. For example, an expression of the form $X{:}P^{\langle e,t\rangle}{:}S/Nm$ and an expression of the form $Y{:}y^e{:}Nm$ can combine to yield an expression of the form $Y\ X{:}P^{\langle e,t\rangle}\ (y^e){:}S$. (Thus, we can construct the categorized interpreted expression $jan\ sneezes{:}snz^{\langle e,t\rangle}\ (j^e){:}S$.) To make sentences with quantificational subjects, we need a similar, but different, rule: an expression of the form $Q{:}\mathrm{Q}^{\langle\langle e,t\rangle,t\rangle}{:}S/(S/Nm)$ and an expression of the form $X{:}P^{\langle e,t\rangle}{:}S/Nm$ can combine to form an expression of the form $Q\ X{:}\mathrm{Q}^{\langle\langle e,t\rangle,t\rangle}\ (P^{\langle e,t\rangle}){:}S$. Both these rules combine an expression with syntactic category of the form A/B and an expression with syntactic category B, but the two rules cannot be collapsed, since the order of combination differs: in one case, the B-category expression precedes the A/B-category expression, in the other case, it follows. There is a possible simplification which Montague took advantage of: for each expression of the form $X{:}i^e{:}Nm$, there is a corresponding expression of the form $X{:}\lambda P^{\langle e,t\rangle}.P(i^e){:}S/(S/Nm)$. (The transition from Nm to $S/(S/Nm)$ is a special case of what is often referred to as *type-lifting*.) If we combine the type-lifted form $jan{:}\lambda P^{\langle e,t\rangle}.P(j^e){:}S/(S/Nm)$ with $sneezes{:}snz^{\langle e,t\rangle}{:}S/Nm$ by an application – this time with a second order argument S/Nm, rather than with an atomic argument – the result is $jan\ sneezes{:}(\lambda P^{\langle e,t\rangle}.P(j^e))snz^{\langle e,t\rangle}{:}S$. The first and the third dimensions are the same as those we obtained earlier, on the assumption that *jan* was typed Nm, and a simple calculation using the interpretive rules for abstraction and application shows that the medial term has the same value in both cases. Moreover, by treating all names as belonging to the higher category $S/(S/Nm)$, rather than Nm, we can generalize the rule of application so that any expression of the form $X{:}\xi{:}A/B$ can combine with any expression of the form $Y{:}\eta{:}B$ to form the expression of the form $X\ Y{:}\xi\ (\eta){:}A$. For example, given the lexical assumptions above, two such applications yield an analysis of *every teacher sneezes*:...:S, whose middle term we leave for the reader to supply. The application of several β-reductions will show the equivalence of this term with the normal form $\forall x^e.(tch^{\langle e,t\rangle}\ (x^e) \rightarrow snz^{\langle e,t\rangle}\ (x^e))$.

To extend this analysis to transitive verbs, one must find a way to deal with both names and quantifiers in object position. This involves two questions: is it possible to transfer the syntactic category and semantic type of quantifiers in subject position to quantifiers in object position? How is it possible to introduce scope ambiguities which arise when quantifiers are in both subject and object position?

Montague dealt with the first question in effect by appealing to a form of type-lifting. Instead of assigning transitive verbs the type $(S/Nm)/Nm$ and the corresponding semantic type $\langle e, \langle e,t\rangle\rangle$, he assumed that each (extensional) transitive verb (such as *respects*) is associated with a corresponding constant (such as $respect_*^{\langle e,\langle e,t\rangle\rangle}$) of type $\langle e, \langle e,t\rangle\rangle$, but the verb itself takes a quantifier argument and the interpretation of the quantifier argument is applied to the object argument of the verb. Thus, we have such lexical assumptions as *respects*: $\lambda\mathrm{Q}.\lambda x.\mathrm{Q}\lambda y.\ (respect_*(y)(x)){:}(S/Nm))/(S/(S/Nm))$. We can combine *respects* with *every teacher* to form the verb phrase *respects every teacher* of syntactic category S/Nm, whose semantic value is equivalent to the β-normal form expression $\lambda x.(\forall y^e.(tch(y) \rightarrow respect_*\ (y)(x)))$.

This use of type-lifting reconciles the monadic quantifier type with nonsubject syntactic positions. But if multiple quantifiers appear in a sentence, their relative scope depends completely (on this account so far) on the order of combination: scope is inverse to the order of combination, with the earliest quantifier added having the narrowest scope and the last quantifier added the broadest scope. Montague offered an account of scope as well, an account based on the role of variables in such systems as first-order logic.

Suppose we admit the lexical element $she_1{:}\lambda P^{\langle e,t\rangle}.(P(x_1^e)){:}S/(S/Nm)$. And suppose we allow a quantifier $Q{:}\mathrm{Q}{:}S/(S/Nm)$ to combine with a sentence $sent{:}\phi{:}S$ to form the result $sent[Q/she]{:}\mathrm{Q}(\lambda x_1.\phi){:}S$. In the first dimension, $sent[Q/she]$ is defined as the result of replacing the first occurrence of *she* in *sent* (if there is one) with Q and replacing subsequent occurrences of *she* with appropriate pronouns; in the second dimension, we apply the interpretation

of the quantifier to the result of applying the abstraction operator λx_1 to the interpretation of the sentential argument. For our purposes, the interesting case arises when the argument sentence is built up from the element she_1, as is the case for *some teacher respects* she_1:$\exists x(tchr(x) \wedge respect_* (x_1) (x))$:$S$. If we now combine this expression with the quantifier *every student*:$\lambda Q.\forall z.(st(z) \rightarrow Q(z))$:$S/(S/Nm)$, the resulting sentence has the form *some teacher respects every student* and its interpretation (relative to this analysis) is equivalent to $\forall z.(st(z) \rightarrow \exists x(tch(x) \wedge respect_*(z) (x)))$, with the universal quantifier taking wide scope over the existential quantifier. When the sentential argument contains multiple occurrences of she_1, Montague's account provides a treatment of (sentence-internal) bound anaphora – a treatment that is rather rudimentary in terms of empirical coverage, but completely rigorous in terms of its model-theoretic foundations. As stated, this mode of combination is resource-insensitive, since it is compatible with a vacuous form of quantifying-in as well. In this account, the form she_1 is critical both for dealing with scope ambiguities and for dealing with anaphora. Its role is quite analogous to the individual variables in standard presentations of first-order logic (or indeed, in the standard presentation of λ-terms above). In dealing with more complex sentences than the extremely simple ones considered here, more than one variable is needed. In order to ensure that there would always be enough variables, Montague admitted denumerably many of them (she_1, ..., she_n, ..., and for each distinct variable, his fragments contain a distinct rule of quantifying-in (since the quantifying in rule must link the form of the syntactic variable and its interpretation with the abstraction operator used in the statement of the interpretation of the result).

The extensional part of the fragments that Montague introduced are much richer than we have been able to indicate above. They also include a form of relative clauses and treatments of coordination for sentences, verb phrases, and quantifiers. The use of λ-terms makes the interpretive properties of these constructions especially perspicuous. Like the quantifying-in rule, the relative clause rule depends on the variable-like terms she_1, and in fact there is a family of relativization rules, one for each variable, just as in the case of the quantifying-in rule. The n-th such rule combines a common noun ζ:ζ':CN and a sentence ϕ:ϕ':S to form a CN of the form $\zeta\phi$: $\lambda x_n.\ (\zeta'\ (x_n) \wedge \phi')$: CN. In the first dimension, $\zeta\phi$ is the result of transforming occurrences of she_n in ϕ in ways that we shall gloss over. In the second dimension, the abstraction operator λx_n binds an occurrence of x_n passed to ζ' as an argument, as well as any occurrences of x_n that might be free in ϕ'.

The treatment of verb-phrase and quantifier coordination relies on a standard fact from lattice-theory: if L is a lattice and X is any non-empty set, then the function-set L^X of all functions from X to L may be regarded as a lattice as well, with lattice-operations defined *pointwise*. This term means that if f and g are functions from X to L, we define their meet $f \wedge g$ as that function from X to L which maps x in X to $f(x) \wedge_L g(x)$ (where $\wedge_L$ is the meet operator in the lattice L). The λ-term representation of this function is transparent: $\lambda x.\ (f(x) \wedge_L g(x))$. In Montague's application of this fact to natural language coordination, we start with the lattice of truth values – that is, the set $\{0, 1\}$ whose meet operator is the conjunction $\wedge$ and whose join operator is the disjunction operator $\vee$. In addition, we have the non-empty set E of entities, and the set of functions from E to $\{0, 1\}$ is in fact the set $D_{\langle e,t\rangle}$, the set of possible denotations for one-place predicates. Given two one-place predicates γ:γ':S/Nm and δ:δ':S/Nm, we can form their conjunction γ *and* δ:$\lambda x.\ (\gamma'(x) \wedge \delta'\ (x))$:$S/Nm$ and their disjunction γ *or* δ:$\lambda x.\ (\gamma'(x) \vee \delta'(x))$:$S/Nm$. The extension to quantifiers is simply the application of the same technique to the function-set of all functions from one place predicates to the lattice of truth values. The only difference in the semantic dimension – where conjunction, say, takes the form $\lambda P^{\langle e,t\rangle}.\ (Q_1(P) \wedge Q_2(P))$ – is that the abstraction operator involves a higher-order type. Montague showed that coordination and quantification interact in semantically interesting ways. For example, it is possible to derive the intuitive non-equivalence of such pairs of sentences as *a man or a woman found every fish* and *a man found every fish or a woman found every fish*. Since Montague's work, the approach he pioneered has been applied to a much broader range of coordinate structures, including a variety of forms of so-called 'nonconstituent conjunction' – expressions whose properties are at odds with standard phrase-structure accounts, but compatible with functionally-based accounts of syntactic composition, in the sense that it is not hard to say what such expressions combine with and what the syntactic result of this combination is. See Gazdar (1980), Rooth and Partee (1982), Partee and Rooth (1983), Keenan and Faltz (1985), Steedman (1985, 1990), Dowty (1988), and Oehrle (1987).

To move from this extensional account to an intensional model requires several related changes. First, we enrich the system of semantic types with a new modal type constructor $\langle s, -\rangle$. (The symbol s here is not interpreted and the type constructor is essentially a unary operator rather than a binary one.) Second, we

enrich the associated language by introducing a modal operator $\Box$ for necessity and two tense modalities W (future) and H (past). Each of these modalities combines with an expression of type t to form an expression of type t. Finally, there are two functions that deal with the intensional type constructor $\langle s, -\rangle$: if α is an expression of type a, then $\hat{}\alpha$ ('up α') is an expression of type $\langle s, a\rangle$; and if α is an expression of type $\langle s, a\rangle$, then $\check{}$ ('down α') is an expression of type a.

To interpret this language, we assume not only a set E of entities and the set $\{0, 1\}$, but also a set of possible worlds I and a linearly-ordered set of moments of time J. We define the set $D_{\langle s, a\rangle}$ as the set of functions with domain $I \times J$ and co-domain D_a. For example, an expression of type $\langle s, e\rangle$ will be a function that associates each world-time coordinate $\langle i, j\rangle$ with an individual entity in E, and an expression of type $\langle s, t\rangle$ will be a function that associates each world time pair $\langle i, j\rangle$ with a truth value. For any constant of type a, we assume that this information is given to us, as a function that acts on world-time coordinate pairs – elements of the product $I \times J$ – and yields appropriate values at any such coordinate. We record how it is given in terms of a function F that maps constants of type a to functions from $I \times J$ to D_a. Let g be an *assignment function* that associates any variable u of any type (type a, say), with a value in D_a. (Thus, if u is a variable of type e, then $g(e)$ will be an element of E, not a function from world-time coordinates to E).

We now define the value an expression α takes at an arbitrary world-time coordinate $\langle i, j\rangle$. If α is a constant of type a, then $F(\alpha)$ is a function from $I \times J$ to the set of possible denotations of a, and applying $F(\alpha)$ to the worldtime coordinates $\langle i, j\rangle$ yields an element of D_a. The clauses for abstraction, application, equality, and the propositional and first-order operators are the same (though the quantifiers make essential use of the assignment function g and alternatives to it related to the variable involved). The clauses for the modal operators $\Box$, W, and H fix a value relative to one world-time coordinate relative to the value their argument takes at alternative world-time coordinates. For example, we define the value of the necessitation $\Box\phi$ at a given world-time coordinate $\langle i, j\rangle$ to be true if the value of ϕ is true at every world time coordinate, and false otherwise; and we define the value of the 'past-tensification' $H\phi$ at a given world-time coordinate $\langle i, j\rangle$ to be true if there is a time $j' < j$ such that ϕ is true at the coordinates $\langle i, j'\rangle$, and false otherwise. Finally, the value of α of type $\langle s, a\rangle$ at a given world-time coordinate $\langle w, t\rangle$ is taken to be that function h_α with domain $I \times J$ and codomain D_a, such that $h_\alpha(\langle i, j\rangle)$ is the value of α at the world-time coordinates $\langle i, j\rangle$. And the value of $\hat{\alpha}$ (where α is of type $\langle s, a\rangle$), simply applies the function associated with α to the coordinates $\langle i, j\rangle$ of interest.

To adapt our object language to the intensional framework, we introduce one significant change: the basic types Nm and S are still interpreted as elements of E and $\{0, 1\}$, respectively, but the atomic type CN is interpreted as $\langle\langle s, e\rangle, t\rangle$ and, more generally, the interpretation of any functor type of the form A/B is required to belong to the type $\langle\langle s, |A|\rangle, |B|\rangle$, where $|A|$ and $|B|$ are the semantic types associated with the categories A and B, respectively. For example, a one-place predicate belonging to the type S/Nm is to be interpreted as an element of type $\langle\langle s, e\rangle, t\rangle$. And a quantifier is to be interpreted as an element of type $\langle\langle s, \langle\langle s, e\rangle, t\rangle\rangle, t\rangle$. These are not quite compatible, but Montague's rule of application, which combines a quantifier of type $S/(S/Nm)$ and a one-place predicate S/Nm, ensures the semantic well-formedness of the result by applying the interpretation of the quantifier to the intension of the interpretation of the argument. In other cases, Montague introduced expressions 'syncategorematically' without assigning them a syntactic category and only implicitly assigning them a semantic interpretation. For example, the coordinators *and* and *or* are used to make conjunctive and disjunctive sentences (of category t), verb-phrases (of category S/Nm), and quantifiers (of category $S/(S/Nm)$), but they have no syntactic category themselves. (And in this case, it's useful that functors which make sentences associate them with type t, rather than type $\langle s, t\rangle$.)

Montague's syntactic system treats intensional and extensional expressions identically. To distinguish them semantically, Montague introduced a number of 'meaning postulates.' One postulate ensures that proper names are to be interpreted as the same individual across all world-time coordinates. (This fits well with the contrast between the rigid interpretation of names and the nonrigid interpretation of descriptions in such pairs of sentences *If I were Elizabeth II, I would be a Windsor* and *If I were the queen of England, I would be a Windsor*, where we're more likely to accept the first than the second.) The other postulates introduce assumptions which make it possible to deduce the different entailments of extensional and intensional expressions. Consider the interpretations of the extensional one-place predicate *walk* and the intensional one-place predicate *rise*. Each of them is assigned an interpretation of the semantic type $\langle\langle s, e\rangle, t\rangle$. If w is the interpretation of *walk*, however, a postulate ensures that there is an element w_* of the extensional type $\langle e, t\rangle$ with the property that we can define $w(x)$ to hold just in case $w_*(\check{}x)$ holds. In

other words, w is an *intensional lift* of an extensional concept. Properly intensional concepts cannot be reduced to extensional concepts in this way. For further details and analysis, see Montague's original papers, as well as the excellent textbooks by Dowty *et al.* (1981) and Gamut (1991).

The object languages in the various fragments that Montague proposed are rigorously defined, but focus on relatively simple constructions and sometimes introduce devices from the study of formal languages that do not obviously fit. One possible perspective on this work draws on the history of model-theoretic consistency proofs: just as the great 19th century constructions of models of non-Euclidean geometry prove the consistency of geometries in which the parallel postulate fails, Montague's model-theoretic construction of linguistic fragments proves the consistency of languages with intensional constructions, quantification, a limited form of generalized coordination, and modality. At the same time, the rigorous analysis Montague offered of these properties radically improved our understanding of the interactions among these properties in their natural language setting. Montague's functional perspective on composition makes it possible to assign functional types to a broad range of natural language expressions: for example, it is a simple step to move by abstraction from the interpretation of *every teacher* as $\lambda P.\forall x.(tch(x) \rightarrow P(x))$ to an interpretation of *every* itself, as $every{:}\lambda Q.\lambda P.\forall x.(Q(x) \rightarrow P(x)){:}(S/(S/Nm))/CN$. And by expliciting typing quantifiers (rather than treating them syncategorematically, as is the standard syntactical approach in first-order logic), it is natural to ask which elements of this type are actually instantiated in natural language expressions, paving the way for the work on generalized quantifiers by Barwise and Cooper (1981), Keenan and Stavi (1986), van Benthem (1986), Westerstahl (1988), and others in the late 1970s and 1980s, and to the connections between the monotonicity properties of quantifiers and other operators that have played an important role in the analysis of polarity-sensitive expressions. The fact that natural language proper names seem compatible with more than one type led to the investigation of a variety of forms of type-shifting (see van Benthem, 1986; Partee, 1987), leading to the exploration of systems of 'type-inference' and dynamic type-assignment. Finally, Montague's exploration of the relation between a functionally-based syntax and a functionally-based semantics introduced a new paradigm for the study of grammatical composition, one in which grammatical composition can be seen as a multidimensional system of type-inference systems (differentiated by contrasting resource-management regimes), linked abstractly by a common core of shared principles (as in the Curry-Howard correspondence between proofs in intuitionistic implicational logic and λ-terms).

As an example, consider the interaction of syntactic form and semantic interpretation involving infinitival arguments. In general, it is widely assumed that basic syntactic structure has a '*linear*' character. From a functional perspective, this means that it can be modeled perspicuously by using a linear form of reasoning (such as the associative Lambek calculus L or its non-associative variant NL). (In nonfunctional frameworks, the linearity of argument structure has given rise to a range of special purpose *principles*: the θ-criterion of the Government & Binding theory, the Completeness and Coherence principles of LFG.) On the other hand, various infinitival constructions suggest that the interpretations of syntactic arguments are not restricted to a linear resource-management regime, but can be used more liberally. This situation can be modeled directly by pairing a linear functional account of syntactic composition with a multilinear functional account of semantic composition, which we represent here by two systems of λ-terms.

Consider first a verb like *try*. It combines with an *np* and an infinitive to form a sentence, a fact we represent here with the linear implicational type $np \xrightarrow{\otimes} inf \xrightarrow{\otimes} s$. This type does not represent how the properties of the *np* and *inf* arguments contribute to the whole. To represent these, we label this implicational type with two λ-terms. The first involves the interpretive dimension and takes the form $\lambda x^e \lambda P^{\langle e,t\rangle}.try'\,(x, P(x))$. The second is a function involving the dimension of physical form, and the variables ϕ_1 and ϕ_2 range over phonological or orthographical representations: we shall assume it takes the form $\lambda\phi_1.\lambda\phi_2.(\phi_1 tried \phi_2)$. Note that the interpretive term is not linear: the abstraction operator λx^e binds more than free occurrence in its scope. The properties of the two term labels interact with the properties of the type system in the following ways: a *modus ponens* step in the labeled type system combines a structure that is assignable a labeled type of the form $\phi_1 : \sigma_1 : A \xrightarrow{\otimes} B$ with a structure that is assignable a labeled type of the form $\phi_2 : \sigma_2{:}\ A$, and the combination of the two structures is assignable a labeled type of the form $\phi_1(\phi_2) : \sigma_1(\sigma_2) : B$; an 'abstraction step' in the labeled type system allows one to infer that a structure Γ is assignable a labeled type of the form $\lambda\phi.\Phi : \lambda\sigma.\Sigma : A \xrightarrow{\otimes} B$ if the structure consisting of Γ together with the assumption $\phi : \sigma : A$ is assignable a labeled type of the form $\Phi : \Sigma : B$. If we reach a situation in which every upward branch of the proof ends with an 'identity axiom' instance, where the structure on the left and the type on the right are the same, the proof is successful. Structures

like Γ are built up with an operation $\otimes$ that is associative and commutative. In such a system, the labeled types $\lambda\phi_1.\lambda\phi_2.(\phi_1\ tried\ \phi_2) : \lambda x^e.\lambda P^{\langle e,t\rangle}.(Past(try'\ (x,\ P(x)))) : np \underset{\rightarrow}{\otimes} inf \underset{\rightarrow}{\otimes} s$ and $\lambda\phi_2.\lambda\phi_1.(\phi_1 tried \phi_2) : \lambda P^{\langle e,t\rangle}.\lambda x^e.\ (Past(try'\ (x,\ P(x)))) : np \underset{\rightarrow}{\otimes} inf \underset{\rightarrow}{\otimes} s$ are interderivable. In this case, since the types *np* and *inf* are distinct, this means that we can combine the arguments of try in either order, with the same result. (It is also possible to think of the situation as one in which we can combine the arguments in a way that does not depend on the order of application.)

The verb *try* has often been analyzed as a verb whose subject must syntactically control the (missing) subject of the infinitival argument. (On the account offered here, there is no representation of a missing subject of the infinitive: *try* combines directly with an infinitive.) A standard contrast (going back to the insights of Jespersen (1909–1949, 1937)) is to compare the behavior of a verb like try with a 'raising' verb like *seem*. As a first approximation, we might consider the following labeled type adequate for *seemed*. It has the same implicational type as *tried* and an analogous term in the first dimension, but differs in the interpretive dimension: $\lambda\phi_1.\lambda\phi_2.(\phi_1\ seemed\ \phi_2) : \lambda x^e.\lambda P^{\langle e,t\rangle}.\ (Past(seem'\ (P(x)))) : np \underset{\rightarrow}{\otimes} inf \underset{\rightarrow}{\otimes} s$.

There is a better analysis of *seemed*, however, one which accounts for the scope ambiguity observable in sentences with a quantifier in subject position (Jacobson, 1990; Carpenter, 1997; Oehrle, in press). For example, the sentence *Every student seems to be well-prepared* can be construed to mean either that every student seems to have the property that he or she is well-prepared or that it seems that every student is well-prepared. This distinction is directly derivable in the type system described here by assuming that *seemed* combines with a monadic quantifier as its subject, rather than a simple noun phrase. Consider the labeled type $\lambda\phi.(\phi\ seems\ to\ be\ well\text{-}prepared)$: $\lambda Q.(Pres(seem(Q(be\ well\text{-}prepared'))))$:$((np \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s$. This labeled type can combine with a quantifier of type Q:$\lambda P.Q(P)$:$(np \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s$ in this system of type-inference. On the first, the quantifier is the argument and the result (after normalizing the λ-terms) is $Q\ seems\ to\ be\ well\text{-}prepared$: $Pres(seem(Q(be\ well\text{-}prepared')))$. On this analysis, the quantifier has narrow scope with respect to the interpretation of *seem*. On the second analysis, the quantifier is the functor and we must show that the structure labeled by *seems to be well-prepared*, of type $((np \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s$ yields a structure compatible with the argument of the quantifier, namely, of the type $np \underset{\rightarrow}{\otimes} s$. We can derive this result by an abstraction inference, if we can show that the structure built up from *np* and $((np \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s$ yields the type *s*. And we can do this if we can show that the type $(np \underset{\rightarrow}{\otimes} s) \underset{\rightarrow}{\otimes} s$ is derivable from the structure *np*. This is simply the type-lifting rule, which is derivable in this system by abstraction from the structure consisting of $np \underset{\rightarrow}{\otimes} s$ and *np*, which is itself an application. The interpretive term associated with $np \underset{\rightarrow}{\otimes} s$ in this proof is $\lambda x.((\lambda Q.(Presseem(Q(be\ well\text{-}prepared')))(\lambda P.P(x))))$. And in the application of the interpretation of the quantifier to this term, the quantifier outscopes *seem*.

Quantifier scope ambiguities arise in this system without special stipulation. In fact, the type system itself provides four distinct proofs that two quantifiers and a two-place predicate can combine to form a sentence: there are two ways in which the quantifiers can bind the arguments of the predicate and for each of these two ways, two possible scopings. In natural language, the position of the quantifier in the sentence determines which argument it binds. And in the term labeled system described here, the string terms constrain which argument the quantifier binds in exactly the same way. As a result, only the two intuitively available readings are possible. For details, see Oehrle (1994, 1995) and more recent work by Muskens (2003) and de Groote (2001).

Much has happened since Montague's era. Some of the highlights include the application of Montague's basic perspective to the study of generalized coordination (mentioned above), the investigation of branching quantifiers and plural constructions, the development of theories of discourse representation and dynamic forms of Montague Grammar, and new function-based theories of binding and anaphora. Moreover, other forms of type-theory have been investigated as models for linguistic phenomena (see, for example, Chierchia, Partee, and Turner, 1989 and Ranta 1994). In all of these cases, the various forms of the λ-calculus have played a fundamental role.

Opie, Peter (1918–1982) and Iona (b. 1923)

H Kishimoto, Kobe University, Kobe, Japan

© 2006 Elsevier Ltd. All rights reserved.

Peter and Iona got married in 1943. Shortly after they had their first child in 1944, they started their joint work on documenting children's leisure activities, including rhymes, tales, plays, chants, and jokes. Their collaborative efforts resulted in a number of widely recognized scholarly works, all of which were associated with children's folklore. The Opies' most prominent achievement was documenting children's folklore in Britain between the 19th and 20th centuries. Peter and Iona established children's folkloristics as an academic discipline through their cautious research.

The first book *The Oxford dictionary of nursery rhymes* (1951), which was published seven years after Peter and Iona embarked on their research, brings together 550 nursery rhymes (and the later *The Oxford nursery rhyme book* (1955) contains about 800 nursery rhymes and 600 illustrations). Their primary intention in compiling *The Oxford dictionary of nursery rhymes* was "to build up a picture of the surroundings in which the rhymes have thrived, and of the effect they have upon their hearers." Thus, the nursery rhymes are furnished with information on standard texts and variants, the earliest recording of each rhyme, and also illustrations of some possible circumstances of their origins and the changes undergone over the years. One particularly notable feature of *The Oxford dictionary of nursery rhymes* is the consultation of original sources wherever possible; because documentary support has always been sought, the book is known as the first classic scholarly work in folkloristics.

Peter and Iona employed different research methods elsewhere. In *The lore and language of schoolchildren* (1959), they collected children's folklore, such as perennial slang, jokes, jeers, initiation rites, seasonal customs, and superstitious practices from some 5000 children in different parts of Britain rather than consulting written sources. *Children's games in street and playground* (1969) is another instance of the recording of children's games played out in the street and playground, collected directly from children. *The classic fairy tales* (1974) gives 24 well-known children's classic fairy tales in their original forms. A number of books came out even after Peter's death in 1982, including *A dictionary of superstitions* (1989), in which some of the British traditional folklore materials collected by the Opies was compiled by Iona in collaboration with Moira Tatem.

Peter and Iona Opie's distinguished works are recognized worldwide. They were conferred an honorary degree from Oxford University in 1962. Peter Opie served as President of the Anthropology Section of the British Association (1962–1963) and was President of the Folklore Society (1963–64). *Children and their books* (1989) is a volume celebrating the achievements of Peter and Iona Opie, who had an immense impact on British folkloristics. The Opies' collection of about 20 000 children's books, the finest private collection in the world, is now housed in the Bodleian Library at Oxford University.

Background

When light interacts with living tissue, it is scattered, absorbed, and transmitted by molecules and cells. For example, if a lamp emitting white light is pressed against a hand in a dark room, only red light will be observed to be transmitted. This occurs because the shorter-wavelength light at the blue end of the spectrum is scattered and absorbed by the tissue more significantly than longer-wavelength red light. Additionally, physiological changes in the tissue would result in changes of its optical properties. For example, alterations in the volume or oxygenation of the hemoglobin perfusing through the hand would result in a change in the amount of red light being transmitted. This is the basis of pulse oximetry, a practical method for quantitatively monitoring blood oxygenation in patients during surgery. More generally, optical measurements provide a nondestructive means of gathering information about dynamic biochemical and physiological processes in tissues.

It has long been known that the optical properties of neuronal tissue vary as a function of the level of neuronal activity. It was first reported by Hill and Keynes (1949) that invertebrate nerves scatter significantly more white light during increased neuronal activity. In the years subsequent to the Hill and Keynes report, light-scattering measurements have been used to study activity-evoked physiological changes in a variety of *in vitro* and *in vivo* laboratory studies. Since these activity-evoked optical changes can be measured without the use of extrinsic contrast-enhancing agents, they are commonly referred to in the literature as 'intrinsic optical signals' (IOS).

Of all the methods used to measure neuronal activity, IOS methods offer the experimentalist several unique technical advantages. First, IOS techniques are physiologically noninvasive in that they do not require the use of ionizing radiation or contrast-enhancing chemical agents or the insertion of recording electrodes into cells or tissues. Second, since the spatial resolution of IOS measurements is determined by the optics and size of the detector, IOS techniques can measure changes occurring over vastly different spatial scales, from single cells to centimeters of tissue. Third, as a result of continuous improvements in computer and optoelectronic technology, IOS technology is inexpensive in comparison with other functional mapping technology, such as positron–emission tomography (PET) or functional magnetic resonance imaging (fMRI).

In recent years, IOS imaging techniques have been developed to map activity-evoked optical changes in monkey and human cortex. Two categories of IOS brain-mapping techniques are currently being used by investigators. The first involves the use of near-infrared light to map cortical activity in human subjects noninvasively. Although the noninvasiveness of these techniques provides a significant advantage, they suffer from two major drawbacks: (1) the spatial resolution is limited to the theoretical maximum of approximately 0.5 cm, because photons are scattered by the cranium and dura, and (2) because only longer-wavelength light can penetrate bone and dura, noninvasive IOS imaging is limited to near-infrared wavelengths; it is not possible to take advantage of imaging with other wavelengths of the spectrum, which can provide important kinds of physiological information.

The second category of IOS imaging techniques, which is the focus of this article, involves intraoperative mapping of the exposed cortex in neurosurgery patients. Intraoperative IOS mapping has the advantage of being able to provide single-cell resolution at wavelengths throughout the visible and near-infrared spectrum. It allows for the visualization of changes occurring within distinct vascular and tissue compartments with high spatial and temporal resolution. Consequently, intraoperative IOS imaging can yield detailed information about the links between

Background

When light interacts with living tissue, it is scattered, absorbed, and transmitted by molecules and cells. For example, if a lamp emitting white light is pressed against a hand in a dark room, only red light will be observed to be transmitted. This occurs because the shorter-wavelength light at the blue end of the spectrum is scattered and absorbed by the tissue more significantly than longer-wavelength red light. Additionally, physiological changes in the tissue would result in changes of its optical properties. For example, alterations in the volume or oxygenation of the hemoglobin perfusing through the hand would result in a change in the amount of red light being transmitted. This is the basis of pulse oximetry, a practical method for quantitatively monitoring blood oxygenation in patients during surgery. More generally, optical measurements provide a nondestructive means of gathering information about dynamic biochemical and physiological processes in tissues.

It has long been known that the optical properties of neuronal tissue vary as a function of the level of neuronal activity. It was first reported by Hill and Keynes (1949) that invertebrate nerves scatter significantly more white light during increased neuronal activity. In the years subsequent to the Hill and Keynes report, light-scattering measurements have been used to study activity-evoked physiological changes in a variety of *in vitro* and *in vivo* laboratory studies. Since these activity-evoked optical changes can be measured without the use of extrinsic contrast-enhancing agents, they are commonly referred to in the literature as 'intrinsic optical signals' (IOS).

Of all the methods used to measure neuronal activity, IOS methods offer the experimentalist several unique technical advantages. First, IOS techniques are physiologically noninvasive in that they do not require the use of ionizing radiation or contrast-enhancing chemical agents or the insertion of recording electrodes into cells or tissues. Second, since the spatial resolution of IOS measurements is determined by the optics and size of the detector, IOS techniques can measure changes occurring over vastly different spatial scales, from single cells to centimeters of tissue. Third, as a result of continuous improvements in computer and optoelectronic technology, IOS technology is inexpensive in comparison with other functional mapping technology, such as positron–emission tomography (PET) or functional magnetic resonance imaging (fMRI).

In recent years, IOS imaging techniques have been developed to map activity-evoked optical changes in monkey and human cortex. Two categories of IOS brain-mapping techniques are currently being used by investigators. The first involves the use of near-infrared light to map cortical activity in human subjects noninvasively. Although the noninvasiveness of these techniques provides a significant advantage, they suffer from two major drawbacks: (1) the spatial resolution is limited to the theoretical maximum of approximately 0.5 cm, because photons are scattered by the cranium and dura, and (2) because only longer-wavelength light can penetrate bone and dura, noninvasive IOS imaging is limited to near-infrared wavelengths; it is not possible to take advantage of imaging with other wavelengths of the spectrum, which can provide important kinds of physiological information.

The second category of IOS imaging techniques, which is the focus of this article, involves intraoperative mapping of the exposed cortex in neurosurgery patients. Intraoperative IOS mapping has the advantage of being able to provide single-cell resolution at wavelengths throughout the visible and near-infrared spectrum. It allows for the visualization of changes occurring within distinct vascular and tissue compartments with high spatial and temporal resolution. Consequently, intraoperative IOS imaging can yield detailed information about the links between

neuronal activity and hemodynamic changes that is not obtainable with other functional imaging modalities.

Physiological Principles: What Causes Intrinsic Optical Signals in Cortical Tissue?

The optical scattering and absorption properties of brain tissue are correlated with changes in the level of neuronal activity. Such changes are thought to be generated by a combination of at least three physiological mechanisms: (1) changes in blood volume, (2) changes in blood oxygenation, and (3) blood-independent light-scattering changes resulting from ion fluxes and cell volume changes associated with neuronal activity. This last component – blood-independent light-scattering changes – is the major generator of IOS in bloodless *in vitro* preparations such as live cortical tissue slices. However, *in vivo* IOS is dominated largely by the hemodynamic components of blood oxygenation and blood volume.

The way in which blood volume and blood oxygenation generate activity-dependent optical changes in cortex can be understood by considering their optical properties. As Figure 1 shows, the optical absorbance spectra of deoxygenated hemoglobin (Hb) and oxygenated hemoglobin (HbO_2) vary independently as a function of wavelength.

The upper plot (Figure 1A) shows the optical absorption spectra of Hb and HbO_2 (i.e., how much

Figure 1 Optical absorption spectra of hemoglobin: Figure 1A shows the optical absorption spectra of oxygenated and deoxygenated hemoglobin as is typically shown in the published literature. It is a logarithmic plot of the molar extinction coefficient versus wavelength: it shows the amount of light absorbed by hemoglobin at optical wavelengths between 450 nm and 900 nm. The essential points to note are that at points where the graphs cross (i.e., are equal), both oxy- and deoxyhemoglobin absorb the same amount of light and hence are indistinguishable. These points are known as 'isobestic points' and represent ideal wavelengths to measure changes in blood volume. Wavelengths at which the graphs are farthest apart represent points at which the oxygenation state of hemoglobin is maximally distinguishable and hence represent wavelengths that are ideal for measuring changes in blood oxygenations. Figure 1B shows data from 1A replotted linearly; here the difference in optical absorption between oxy- and deoxyhemoglobin is plotted against wavelength, making differences in their optical absorptivity more obvious. Isobestic points, such as 535 nm, are those wavelengths where the graphs touch the x-axis (i.e., oxy- and deoxyhemoglobin absorb the same amount of light at those wavelengths). It can be seen that at 660 nm, the difference in absorptivity is maximal. (These figures were generated from data by W. B. Gratzer, 'Tabulated molar extinction coefficient for hemoglobin in water,' Medical Research Council Labs, London, and N. Kollias, 'Tabulated molar extinction coefficient for hemoglobin in water,' Wellman Laboratories, Harvard Medical School, Boston; compiled and published on the Internet by Scott Prahl.)

light Hb and HbO_2 absorb at each different pure wavelength); since they are plotted logarithmically, subtle features are difficult to distinguish. Hence, these data are replotted in Figure 1B as a single graph of the absolute differences between Hb and HbO_2 optical absorbances. Several features of these spectra are important to note. First, there are several 'isobestic points' – wavelengths at which the absorbances of both Hb and HbO_2 are indistinguishable (e.g., 530–535 nm and 800 nm). Since the absorption spectrum of hemoglobin at these wavelengths is independent of its oxygen state, and hence is dependent only on the total number of hemoglobin molecules (consequence of Beer-Lambert law; see Tinoco *et al.*, 1985), isobestic points represent ideal wavelengths to measure blood volume changes independently of blood oxygenation changes. Since Hb and HbO_2 have identical values at isobestic points, wavelengths representing isobestic points are located where their differences in light absorption vanish (i.e., where the lower graph touches the x-axis). Second, there are wavelengths at which Hb and HbO_2 are maximally distinguishable (660 nm and > 900 nm). Consequently, these 'oxygen sensitive' wavelengths are ideal for optically monitoring changes in the oxygen state of blood and are represented as maximal values in the lower plot.

It is well known that two major hemodynamic changes are evoked by increases in neuronal activity: (1) increases in blood volume and (2) increases in blood oxygenation in the veins draining regions of activated cortex. The cascade of events leading to these activity-evoked hemodynamic changes can be summarized as four steps: (1) firing of action potentials induce a release of signaling molecules that cause small surface arterioles to dilate; (2) the dilation of arterioles is strictly localized over regions of increased neuronal activity and underlies the focal increases in blood volume; (3) blood flow increases dramatically because flow is related to the fourth power of vessel diameter; and (4) large increases in blood oxygenation occur in the veins draining activated tissue because the transit time of hemoglobin in the tissue is dramatically reduced by the increased flow. It is known that the activity-induced changes in cerebral flow are facilitated by dilation of the terminal ramifications of the smallest pial arterioles lying on the cortical surface; the larger arterioles and veins do not dilate and do not play a role in the regulation of activity-evoked changes in cerebral flow (Mchedlishvili, 1986; Moskalenko, 1998; Ngai *et al.*, 1988).

In summary, both blood oxygenation and blood volume changes underlie the generation of IOS *in vivo*. Increases in neuronal firing result in highly localized changes in blood volume (restricted to the microscopic pial arterioles) and less highly localized changes in blood oxygenation (restricted to the venous network). By selecting the appropriate wavelengths, one can select specifically for changes in either blood volume or oxygenation. Because blood volume changes are spatially localized to the smallest pial arterioles near firing neurons, this signal is thought to accurately localize activity in populations of neurons. By comparison, blood oxygenation changes occur throughout the venous network; IOS mapping of blood oxygenation provides a less accurate map of activity, but it provides information about oxygen use during neuronal activity.

Comparison of IOS Mapping with Other Imaging Modalities

Since IOS mapping provides high spatial and temporal resolution, it is not only useful for localizing neuronal activity but can also provide visualization of the spread of activity between cortical areas. This ability to allow dynamic visualization of hemodynamic changes with millisecond resolution is unique to IOS imaging. Other techniques that provide information for the mapping of cortical activity include electroencephalography (EEG), fMRI, PET, and single photon emission computed tomography (SPECT). All of these modalities provide either less spatial or less temporal resolution than does intraoperative IOS imaging. EEG is useful mostly for diagnostic purposes but in some cases can provide lateralization and localization information. EEG techniques provide superior temporal resolution; however, even intracranial EEG has limited spatial resolution and can provide misleading information regarding localization. For example, activity might be initiated at a distance away from the recording site and spread rapidly to the EEG electrodes, thus falsely appearing to originate at the EEG electrode (Sperling, 1997). PET and SPECT can provide less accurate spatial and temporal information than can IOS imaging. For example, regional cerebral blood flow assessed using PET currently has a temporal resolution of 30 sec/image and a spatial resolution of $8 \times 8 \times 4.5\,mm^3$, with fluorodeoxyglucose (FDG)-PET (used in glucose metabolism studies) and SPECT having considerably lower resolutions. The slower temporal resolutions of PET and SPECT further reduce their spatial accuracies; during the spread of activity across the cortex, sites where activity is initiated are averaged together with the paths of propagation, thus 'smearing' spatial information (Roland, 1993).

There are several obvious limitations of intraoperative IOS imaging. First, IOS imaging is limited to mapping activity on the cortical surface. A number of schemes have been proposed to use longer-wavelength

light to reconstruct features from deeper structures; however, all of these schemes suffer from dramatically reduced spatial and temporal resolutions. Second, and most obvious, intraoperative IOS imaging is limited to use in the operating room; direct exposure of cortical areas is necessary for IOS mapping.

Intraoperative Optical Imaging of Language Cortex

Haglund *et al.* (1992) first reported the use of optical imaging for studying language cortex. Figure 2Aa shows a grayscale image of tongue and palette sensory cortex, and Figure 2Ba shows the adjacent Broca's area. Intraoperative electrical stimulation mapping of the cortical surface was first used to identify sites of speech arrest (sites 3 and 4 on grayscale images) and palate and tongue sensory cortex (sites 1 and 2, respectively). Optical images were acquired from Broca's area while the patient silently viewed blank slides while naming objects on slides presented every two seconds. Images obtained during this naming exercise (baseline noise is shown in Figure 2Bb, naming-evoked optical changes in Figure 2Bc) show activation of the premotor cortex, while the sites of stimulation-identified speech arrest yielded optical signal in the opposite directions (black areas in Figure 2Bc). Figure 2Ac shows the area that was activated during tongue movement, which is clearly distinct from the area activated during the naming exercise shown in 2Bc. It should be noted that the optical changes in the premotor cortex during the naming exercise coincide with the cortical areas identified by early PET studies on single-word processing. The optical changes were largest in the anatomical area traditionally identified as Broca's area (the posterior portion of the inferior frontal gyrus, or sites 5, 6, and 7 in Figure 2Ba), and not in those areas identified by where electrical stimulation caused speech arrest (sites 3 and 4).

Figure 3 shows imaging of posterior essential languages sites, or Wernicke's areas, that again were identified with electrical stimulation mapping prior to imaging. Imaging during the naming exercises showed optical changes in these regions of temporal lobe. In the patient shown, two essential languages sites were identified in sites 1 and 2 of Figure 3A; they were deemed essential because naming errors were consistently evoked by electrical stimulation of the cortical surface at these sites. A possible secondary language site (site 3) was also identified by the observation of a single naming error that occurred during three electrical stimulation trials at this site. As the surgical removal of cortical tissue anterior to the thick black line (shown in Figure 3A) neared sites 4 and 5, the patient's language deteriorated. Figure 3B shows optical imaging changes acquired during a naming exercise superimposed on the grayscale image of the cortical surface. Before the surgical removal, optical changes were found at the essential sites (1 and 2) and

Figure 2 Figure 2A*a* shows the exposed cortical surface of a human patient; anterior, left; posterior, right; superior, top; and Sylvian fissure, bottom. Asterisks on the cortical surface serve as reference points for comparison between A*a* and *b* and B*a* and *b*. Scale bar, 1 cm. Numbered boxes represent sites where electrical cortical stimulation (4 mA) evoked palate tingling (1), tongue tingling (2), speech arrest – Broca's area (3,4), and no response (11, 12, 17, 5). A*b*, control image before tongue movement. A*c*, image collected during tongue movement. B*a*, Cortical surface from the same subject with the image translated slightly forward to incorporate more of the premotor cortex. In other premotor sites (6 and 7), no change in language was found during electrical stimulation of the cortex. The patient viewed blank slides (control) and was then required to name pictures appearing every 2 seconds. B*b* and *c*, images acquired during naming tasks. Control image (B*b*) compared with naming image (B*c*) shows that the maximum optical changes are located in the premotor region. (Figure adapted from Haglund, Ojemann, and Hochman. [1992]. *Nature 358*, 670.)

Figure 3 (A) image of the cortical surface; anterior (a), inferior (i), posterior (p), Sylvian fissure (sf), superior temporal gyrus (STG), and middle temporal gyrus (MTG). Scale bar, 1 cm. Sites 1 and 2 were identified as essential for speech. At site 3, one naming error in three stimulation trials was made. Stimulation in all unlabeled boxes did not cause errors in naming slides. Following cortical mapping of language and optical imaging, the temporal lobe cortical tissue to the left of the thick line was surgically removed while the patient's language was tested. As the surgical removal reached the asterisks (sites 4 and 5), language deteriorated. (B) graphic overlay of the optical changes in Wernicke's area during the naming task. The largest optical changes are in the region of essential and secondary language sites and not in the more anterior cortex. In these nonessential regions, the optical changes are restricted to the blood vessels (i.e., the Sylvian fissure vessels in the top left of the figure). (Figure adapted from Haglund, Ojemann, and Hochman. [1992]. *Nature 358*, 670.)

secondary language regions (sites 3–5). The anterior cortical regions, without language disruption during stimulation mapping (unlabeled boxes in Figure 3A), showed no significant optical changes during the naming exercise except along blood vessels. Note that both the essential and secondary language sites (1–5 in Figure 3A) yielded significant optical changes, though the magnitudes of the optical changes in the secondary sites were less than those of the essential language sites. This finding suggests that optical imaging can distinguish and identify essential and secondary language areas that must be preserved during neurosurgical procedures to prevent language deficits.

Conclusions

Because of its high spatial and temporal resolutions and its ability to selectively map changes in either blood volume or blood oxygenation, intraoperative optical imaging has the potential to be a valuable experimental tool to study cortical physiology and functional processing. Recent work with high magnification reported by Haglund and Hochman (2004) shows that IOS mapping can quantitatively measure oxygenation and volume changes occurring within the distinct microvascular compartments during neuronal activation. Such studies may be valuable in shedding further light on the physiological links between neuronal firing and cerebral hemodynamics. Practically, IOS mapping has the potential to be a powerful clinical tool for the localization of essential and secondary language sites and to provide intraoperative monitoring during neurosurgical procedures.

LFG as the Representational Basis of OT Syntax

Optimality Theory (OT) as such is not a linguistic theory, but rather it is a way of interpreting constraints, as might be expressed in the elements of any theory. The fundamental idea of OT is that constraints are not interpreted in an all-or-nothing fashion, as in most previous generative approaches to linguistics, but rather, constraints are ranked with respect to each other, such that lower-ranking constraints may be violated in order for higher-ranking ones to be respected.

As a constraint-based declarative grammatical formalism, LFG lends itself directly to an OT interpretation (Bresnan, 2000b). A standard LFG analysis relates a functional structure (f-structure), which encodes information about the functional relations between the parts, information such as what is the subject and what is the predicate, what agreement features are present, and so on, with a constituent structure (c-structure), the overt expression of that functional information, which is a phrase structure tree encoding phrasal dominance and precedence relations.

LFG as the Representational Basis of OT Syntax

Optimality Theory (OT) as such is not a linguistic theory, but rather it is a way of interpreting constraints, as might be expressed in the elements of any theory. The fundamental idea of OT is that constraints are not interpreted in an all-or-nothing fashion, as in most previous generative approaches to linguistics, but rather, constraints are ranked with respect to each other, such that lower-ranking constraints may be violated in order for higher-ranking ones to be respected.

As a constraint-based declarative grammatical formalism, LFG lends itself directly to an OT interpretation (Bresnan, 2000b). A standard LFG analysis relates a functional structure (f-structure), which encodes information about the functional relations between the parts, information such as what is the subject and what is the predicate, what agreement features are present, and so on, with a constituent structure (c-structure), the overt expression of that functional information, which is a phrase structure tree encoding phrasal dominance and precedence relations.

In OT-LFG, the INPUT is taken to be an underspecified f-structure that represents the main grammatical information that a given sentence expresses, but without any representation of surface (and therefore language-specific) features of expression. As described above, f-structures have the right properties for this role, being representations of language-invariant grammatical information, especially once morphological information is properly factored out (Frank and Zaenen, 2002). For example, the INPUT representation of a transitive clause would include the predicate, its argument structure, semantic information about the arguments of the predicate, and tense and aspect information (cf. (1)).

The OUTPUT candidates are pairs of c-structure/f-structure pairs; (1) shows the general architecture of input-output relations in OT-LFG, based on Bresnan (2000a: 26):

(1) INPUT OUTPUT CANDIDATES

For simplicity, just three potential candidates are shown, each having an f-structure that is subsumed by the INPUT (in other words, each contains the same or more information, but no conflicting information), and each having a different c-structure form. From this point, the evaluation constraints determine an OUTPUT winning candidate relative to an INPUT. The indices on the c-structure nodes are standard LFG notations to indicate how the f-structure information of that node participates in the information carried by the whole clause.

The constraints for evaluation in OT fall into two types:

(2a) Faithfulness constraints, which prefer the output(s) that most closely represent the INPUT information.

(2b) Structural markedness constraints, which favor or disfavor certain types of structure.

Kuhn (2001, 2003) has proposed that the f-structure of the OUTPUT must be subsumed by that of the INPUT. Hence, a candidate OUTPUT with only one GF, say, a SUBJ, would not be a candidate for the INPUT in (1), for the INPUT requires two GFs. Note, though, that the INPUT does not specify which argument is subject and which is object: this is a matter for individual languages to choose, in their candidate evaluation (Aissen 1999; Sells 2001a; Asudeh 2001).

The faithfulness relations of OT-LFG hold between the two parts of each OUTPUT candidate: roughly, semantic faithfulness must hold from the c-structure to the f-structure (these would be OT's DEP constraints), and expressive faithfulness must hold from the f-structure to the c-structure (MAX constraints). The way that MAX and DEP constraints work can be illustrated using a familiar case, namely that of '*do*-insertion' in English, as in (3a), with the f-structure in (3b). Following the analysis of *do* proposed in Grimshaw (1997), and updated in the OT-LFG setting by Bresnan (2000b) and Kuhn (2001, 2003), the PRED information will be as shown in (3c); but this information is not represented in the f-structure when *do* is used as a dummy verb. In other words, the dummy use of *do* is unfaithful to the PRED information: semantically-based information associated with the word in c-structure is not matched in the f-structure. The information fails to flow from c-structure to f-structure, which is a DEP violation in Kuhn's proposal. On the other hand, the morphological inflection on *did* can and will express the TENSE PAST information in the INPUT. Intuitively, this information (correctly) flows from f-structure to c-structure, as satisfaction of a MAX constraint.

(3a) Manny did not sleep.

(3b) $\begin{bmatrix} \text{SUBJ} & [\text{PRED 'Manny'}] \\ \text{PRED} & \text{'sleep . . .'} \\ \text{TENSE} & \text{PAST} \\ \text{POL} & \text{NEG} \end{bmatrix}$

(3c) *did*	V, (↑ TENSE) = PAST	used in b.: satisfaction of MAX
	(↑ PRED) = 'do < *x* >'	not used in b.: violation of DEP

Although the second line of (3c) contains information that does not appear in the f-structure, and hence represents unfaithfulness, the use of dummy *do* is necessitated by a higher ranking constraint on English syntax, to the effect that requires negation to be expressed in construction with an overt (auxiliary) verb in INFL (cf. NEG-TO-I in Bresnan [2000b; 368ff]).

The structural markedness constraints of OT-LFG penalize or favor different kinds of structure, from affixes on words to the positions of particular elements in complex syntactic structures, and include alignment

constraints (see the section Linear Order). In other words, markedness constraints are evaluated with respect to the c-structure part of each candidate. For example, a high-ranking constraint penalizing the functional category IP, or alternatively its head I, would eliminate the middle candidate in (1), rooted in IP.

Many aspects of surface syntactic variation across and within languages are correlated with discourse or contextual features, which are arguably not directly represented in f-structure. For example, the expression of topic and focus leads to surface variation in some languages in the form of scrambling or null expression (zero pronouns), and this information has to be represented. Such 'Information Structure' properties, or more basic properties such as newness or prominence (Vallduví, 1992) have figured widely in OT analyses (Choi, 1999, 2001; Lee, 2001, 2003; Morimoto, 2000).

In addition to information structure, lexical semantic properties, expressed as part of argument structure, may also be considered in the INPUT, in those cases where it is relevant. Morphosyntactic expression may be sensitive to such Proto-Agent and Proto-Patient properties of volitionality, causality, sentience and affectedness, as well as other thematic properties of arguments, leading to different surface expressions across languages, whether those differences are manifest through surface order, grammatical functions, case morphology, head-marking agreement, or any other morphosyntactic device (Asudeh, 2001; Lee, 2001; Sharma, 2001).

In closing this introductory section, I would point out that in comparison to other styles of OT syntax, based on the Minimalist syntax model of Chomsky (1995) and involving a serial derivation of each candidate, such as the 'derivation-and-evaluation' model (Broekhuis and Dekkers, 2000; Broekhuis, 2000), or the 'local optimization' model (Heck and Müller, 2000; Müller, 2001), the OT-LFG model of syntax is a much purer instantiation of the original OT conception: a constraint-based direct evaluation of direct INPUT-OUTPUT relations. Additionally, the declarative nature of the system, and the fact that faithfulness constraints relate the c- and f-structure parts of each candidate, means that there are no ill-formed representations or derivations, in distinction to typical OT analyses based on Minimalist syntax. For example, it is assumed that an 'operator' such as a *wh*-phrase must move to the specifier position of a functional head, to check the *wh*-feature (Chomsky, 1995). Adopting constraints from Grimshaw (1997), such *wh*-movement arises from a ranking OP-SPEC $\gg$ STAY, where the latter constraint forbids movement. A *wh-in-situ* language would have the ranking STAY $\gg$ OP-SPEC (Grimshaw, 1997: 404). In such languages, the *wh*-feature would simply remain unchecked in the derivation. In the OT-LFG model, we might posit exactly the f-structure for a *wh*-movement and a *wh-in-situ* example, associated with different c-structures. Each structure would be independently well-formed; what would differ would be the profile of faithfulness and markedness constraints relating f- and c-structures.

Morphology Competes with Syntax

Much work in LFG and OT-LFG has investigated in what ways morphological and syntactic structures carry the same kinds of information, summarized in the phrase 'morphology competes with syntax' (Bresnan, 1998: 86). I will use this theme to organize my discussion of the main research areas that have been explored in OT-LFG.

Harmonic Alignment

One key idea that has been developed in OT syntax is the role of Harmonic Alignment: various scales of different kinds of markedness align with each other to express 'regions' of markedness in grammars, which in turn can generate OT markedness constraints, using the formal mechanism of Harmonic Alignment from Prince and Smolensky (1993). Harmonic alignment also directly provides an account of 'markedness reversal,' the situation where what is marked for one type of element (say, subjects) is unmarked for another (say, objects). This technique is presented with many insightful and important consequences in Aissen (1999) and Aissen (2003). For example, from the markedness scales in (4), which rank Agent above Patient among the thematic relations, and Subject above Object among the grammatical relations, Harmonic Alignment can be used to generate the OT constraints in (5):

(4a) Ag > Pt
(4b) Su > Ob

(5a) *Pt/Su $\gg$ *Ag/Su
(5b) *Ag/Ob $\gg$ *Pt/Ob

These OT constraints disfavor Patient subjects relative to Agent subjects, and show the converse preference for objects. These constraints must be interspersed with other constraints to generate complex interactions that characterize any real voice systems in natural language. However, the primary force in (5) lies in the relative ranking, which is fixed

in each of (5a)–(5b), due to the mechanism of Harmonic Alignment. These ranked constraint sets correctly characterize the fact that for a two-place predicate with Agent and Patient arguments, the unmarked linking will always be Ag=Su and Pt=Ob, as these linkings violate only the lower constraints in (5).

This is a mere sketch of a much richer system developed by Aissen. Other applications of these ideas to voice systems, more specifically expressed in LFG, can be found in Asudeh (2001) and Sells (2001a) (see also the next subsection).

Markedness in Morphological Expression

There are three different linguistic possibilities for the realization of some abstract category: morphologically unmarked expression, morphologically marked expression, and no expression at all. The simplest OT competition between candidates favors one candidate expression over another, which effectively covers the situation of expression vs. no expression: certain expressions are just impossible, in other words, ungrammatical.

For marked vs. unmarked expression, Aissen (2003) proposed the technique of local conjunction with *Ø, a constraint that disprefers null morphological structure – in other words, a constraint that prefers morphological marking. Let us consider again Active vs. Passive: Passive is a marked morphosyntactic form with respect to Active, and the argument-function linking is also marked, for the subject is not the thematically highest argument. To illustrate the effect of *Ø more directly, let us think of a simple transitive input with Agent and Patient arguments. If the evaluation grammar contains a constraint like *Su/Pat that says 'avoid Patient subjects,' this would block passive-like outputs completely. In contrast, the constraint [*Su/Pat & *Ø] says 'avoid Patient subjects in the absence of morphological marking' and has a different effect on output: it allows passive-like outputs just in case the form has some overt morphological (or morphosyntactic) marking. This is how OT syntax captures the intermediate case of marked expression. Completing the picture, there is a countervailing force in the grammar, the constraint *STRUC, which prefers the absence of (morphological) structure. This allows the requirement of overt marking to be 'turned off' at certain points, as I now illustrate with an example from Sharma (2001), who analyzes patterns of subject and object registration by case clitics in Kashmiri. To choose just one part, there is the familiar phenomenon that subjects in perfective clauses are specially registered (by Ergative case) while subjects in nonperfective clauses are not, and take the default Nominative case. Sharma proposes the constraints in (6a) that reflect the intuition that she develops, that perfective clauses (with subjects) are more marked than imperfective clauses; conjoining these with *Ø gives the constraints in (6b):

(6a) *SU/PERF $\gg$ *SU/IMPERF
(6b) [*SU/PERF & $*Ø_C$] $\gg$ [*SU/IMPERF & $*Ø_C$]

(6b) indicates that it is more marked for perfective clauses with subjects to have no morphosyntactic registration than it is for imperfective clauses: in other words, if any form is marked, it will at least be the one expressing a perfective clause. If the constraint *STRUC is interpolated between the two constraints in (6b), giving the ranking [*SU/PERF &$*Ø_C$] $\gg$ *STRUC $\gg$ [*SU/IMPERF & $*Ø_C$] means that there is special registration of the subject when the verb is in perfective aspect, but otherwise every morphological marker is penalized. So this means that subjects are registered – by clitics, in the case of Kashmiri – in perfective but not imperfective clauses, and as the relative ranking of the two constraints [*SU/PERF & $*Ø_C$] and [*SU/IMPERF & $*Ø_C$] is fixed in that order by Harmonic Alignment, a typology of just three language types emerges: languages in which there is no overt registration of subjects, regardless of clause type (*STRUC is ranked highest), languages like Kashmiri, and languages in which subjects are registered in both clause types (*STRUC is ranked lowest).

Hierarchical Structure

The position of the finite verb in a clause can illustrate what syntactic markedness constraints are like and how they interact. Here I present familiar facts from French and English (Emonds, 1978), two languages with underlying SVO structure, and with very similar clausal syntax. Both languages place the subject in the Specifier of IP (SpecIP). If IP is present, its head I may also be present, and the languages differ in precisely if and how they realize I (Bresnan, 2000a; Sells, 2001b).

English The facts of interest here are summarized in (7), based on the data in (7a)–(7d) which show that the adverbs are adjoined to VP and that only auxiliary verbs are in the pre-adverb position, namely the I head of IP.

(7) English: IP is headed only if an auxiliary verb is present.
(7a) Anna has often read novels.
(7b) ??Anna often has read novels.
(7c) *Anna reads often novels.
(7d) Anna often reads novels.

The structures for the grammatical examples are shown in (8), as annotated LFG c-structures.

(8a)

(8b)

Note that in LFG, V is directly generated in I; it is not moved there (as there is no 'prior' structure). In (8a), IP lacks any head position I, as there is no overt element filling it.

French In French, the facts are slightly different, given in (9), with the associated structures in (10):

(9) French: IP is always headed, by any finite verb.

(9a)	Anna	a	souvent	lu	des	romans.
	Anna	has	often	read	(some)	novels

(9b) *Anna souvent a lu des romans.

(9c)	Anna	lit	souvent	des	romans.
	Anna	reads	often	(some)	novels

(9d) *Anna souvent lit des romans.

(10a)

(10b)

Adopting the analysis of Grimshaw (2000) whereby I and C are categorially similar to V, and are literally 'extended projections' of it (though no CP structures are shown here). I is the first functional projection of V, and C is the second. A formal construction of this in LFG can be found in Bresnan (2001: 100–101); the relevant details are given in (11):

(11) Extended Projections – Grimshaw (2000)
(11a) V = [+V, −N, FØ]
(11b) I = [+V, −N, F1]
(11c) C = [+V, −N, F2]

Once we assume that V can be generated in I or C (as well as the head of VP), we can formulate constraints that favor one type of structure or another, such as those in (12).

(12) Constraints for clausal positions:

(12a) PURE-PROJ: Projections are pure; violated by lexical heads in functional projections. Specifically, V in I = 1 violation; V in C = 2 violations. (Cf. PURE-EP in Grimshaw [1997: 393].)

(12b) OB-HD(FP): a functional projection (IP or CP) should have an obligatory head in c-structure; violated by a headless IP, etc. (from Grimshaw, 1997).

(12c) *Lex-in-I: don't allow a lexical (i.e., nonauxiliary) V in the functional head position I. This was proposed by Grimshaw (1997), and Bresnan (2000b), to account precisely for the behavior of English auxiliaries.

The effects of (12a) could alternatively be captured in a movement framework via the constraint STAY: don't move – in this case, forbidding movement from V to I (Grimshaw, 1997; Vikner, 2001).

Now we look at the constraint interactions. (12a) has the effect that V in I heading IP violates PURE-PROJ, and so OB-HD(FP) ≫ PURE-PROJ will prefer a headed IP to an unheaded IP, and so on. More generally, (12a) prefers lower heads, while (12b) prefers higher heads. The constraint in (12c) bars lexical categories in functional head positions: it is violated by a lexical verb in I, for example, but is not violated by an auxiliary verb in I. For English, this constraint is necessarily ranked quite high, as only auxiliaries may appear in I.

(13a) PURE-PROJ ≫ OB-HD(FP)
(it is more important not to express I [as V] than to give IP a head; so I is never expressed)

(13b) Lex-in-I ≫ OB-HD(FP)
(it is more important not to express I with a lexical category [verb] than to give IP a head; so I is only ever expressed as an auxiliary)

(13c) OB-HD(FP) ≫ PURE-PROJ
(it is more important to give IP a head than not to express I; so I is always expressed)

One important observation that illustrates the predictive power of OT (relative to a given set of constraints) is that every structure that violates *Lex-in-I also violates PURE-PROJ, but not vice versa. This corollary has precisely the effect that nonlexical verbs may show special positioning in contrast to lexical verbs, but not vice versa. This result is exactly as it should be, as special positioning is the hallmark of a restricted class (of verbs), which we would then classify as auxiliaries.

Using the constraints above, English has the ranking shown, and just two candidates are considered for each relevant case, namely, a structure with only a main verb (the [1] candidates), and a structure with an auxiliary verb as well (the [2] candidates). The [a] candidates have the first verb in the structure in the higher head position, I, and the [b] candidates have the first verb inside VP.

(14) English

		*Lex-in-I	OB-HD(IP)	PURE-PROJ
[1a]	$[_{IP}$ NP $[_{I'}$ V $[_{VP}$ Adv $[_{VP}$ NP]]]]	*!		*
[1b]	☞ $[_{IP}$ NP $[_{I'}$ $[_{VP}$ Adv $[_{VP}$ V NP]]]]		*	
[2a]	☞ $[_{IP}$ NP $[_{I'}$ Aux $[_{VP}$ Adv $[_{VP}$ V NP]]]]			*
[2b]	$[_{IP}$ NP $[_{I'}$ $[_{VP}$ Aux $[_{VP}$ Adv $[_{VP}$ V NP]]]]]		*!	

Here, the highest ranking *Lex-in-I knocks out the [1a] candidate, meaning that [1b] (=(8a)) is the winner in the competition for the structures with a main verb only; with an auxiliary present, OB-HD(FP) plays the deciding role, favoring [2a] (=(8b)).

Moving on to French, the highest ranking of OB-HD(FP) gives both [a] candidates as immediate winners, and these are the structures in (10).

(15) French

		OB-HD(IP)	*Lex-in-I	PURE-PROJ
[1a]	☞ $[_{IP}$ NP $[_{I'}$ V $[_{VP}$ Adv $[_{VP}$ NP]]]]		*	*
[1b]	$[_{IP}$ NP $[_{I'}$ $[_{VP}$ Adv $[_{VP}$ V NP]]]]	*!		
[2a]	☞ $[_{IP}$ NP $[_{I'}$ Aux $[_{VP}$ Adv $[_{VP}$ V NP]]]]			*
[2b]	$[_{IP}$ NP $[_{I'}$ $[_{VP}$ Aux $[_{VP}$ Adv $[_{VP}$ V NP]]]]]	*!		

Linear Order

In Grimshaw's work, the X′ projections of the verbal head and the clausal functional categories above it share categorial features. In LFG, each (nonroot) node sharing features with V is an f-structure head, annotated ↑=↓, thereby extending the clausal structure above VP (Bresnan, 2000b; Bresnan, 2001; and Sells, 2001b, who refers to the relevant set of nodes as the 'clausal spine').

(16) Clausal Spine: The spine of the clause is every node in the extended projection of the head, that is, any node sharing (categorial) features with the verbal head, including V, V′, VP, I, I′, IP, C and C′.

Now, a simple approach to basic ordering properties within the clause can be given with the constraints in (17), which are alignment constraints (McCarthy and Prince, 1993), which align the edge of a constituent with the edge of some larger domain containing that constituent. For example, the natural constraint TOPIC-L (Choi, 1999; Sells, 2001b) would be understood to align a topic constituent with the left edge of the clause that contains it. In contrast, the alignment constraints in (17) align within the domain of the local subtree. Nevertheless, the intuition that they express is that heads prefer to be initial, both locally (within the immediate constituent) and globally (within the clause), expressed by Head-L (Grimshaw, 1997) – 'heads on the left'; countering this is Spine-R, – 'everything on the right' – taking the idea from Sells (2001b) about a preference for right-branching structures.

(17) Asymmetric Alignment Constraints (Sells, 2001b)
(17a) Head-L: X^0 head aligns left in its immediately containing constituent.
(17b) Spine-R: Every node in the spine aligns right in its immediately containing constituent.
